Congress Adjourns . .
Federal Employees' Health Insurance . .
Medical Requirements for Airplane Pilots . .
Cases of Poliomyelitis . .

CONGRESS WINDS UP LONG SESSION

Congress, in its longest session since 1951, approved some significant legislation but failed to act on other important bills both of general nature and of particular interest to the medical profession.

Congressional decisions are expected next session, which will begin Jan. 6, on most of the pending major legislation.

In the waning hours of this year's session—which ended shortly before 6:30 a. m., EDT, Sept. 15—the House completed congressional approval of a voluntary health insurance program for federal employees.

Another bill of interest to physicians, which was approved earlier, was a catch-all housing measure with provisions pertaining to health care. The draft of physicians and dentists was continued in an extension of the military draft.

Congress also appropriated hundreds of millions of dollars for medical research, medical care, hospitals, and related programs.

The Forand and Keogh-Simpson bills were the two measures of greatest concern to physicians left untreated.

Despite the vigorous opposition of doctors and allied health groups, proponents of the Forand bill are expected to make a strong drive for congressional approval of it next year. It would increase social security taxes to help finance health care for the aged.

Indications are that the Senate Finance Committee will vote early next session on a modified version of the Keogh-Simpson bill, which would permit physicians and other self-employed persons to defer federal taxes on income put into private retirement plans.

The House Commerce Committee also postponed until next year action on a Senate-approved bill authorizing a 50-million-dollar annual program for cooperation in international medical research.

In addition to the draft and housing bills, important general legislation approved by Congress included statehood for Hawaii, a strong labor reform bill, a one-cent-per-gallon increase in the federal tax on gasoline, increased pensions for veterans with non-service-connected disabilities, an increase in the interest rate on savings bonds, a higher national debt ceiling, a two-year extension of the life of the Civil Rights Commission, and continuation of the foreign aid program, with a 3.2-billion-dollar appropriation.

Congress appropriated a total of about 73 billion dollars, about 1 billion less than President Eisenhower requested. Appropriations included 400 million dollars for medical research; $88,800,000 for Medicare; $186,200,000 for the Hill-Burton program of federal aid for hospital construction; 30 million dollars for medical research facilities; and 35 million dollars for medical research facilities other than general hospitals.

Despite the heavy Democratic majorities in the House and Senate, President Eisenhower was in the legislative driver's seat most of the time. The President's new assertion of leadership was surprising in view of the fact that the political power of a "lame duck" president usually wanes in his closing years in the White House.

Aided by the nation's economic recovery, the President used the veto—and the threat of it—to block or at least trim down big spending programs of the Democrats. His one major setback on such legislation came when Congress overrode his second veto—the 146th since he became president—of a public works bill which carried money for dams and similar projects in most congressional districts. It marked the first time Congress had overridden an Eisenhower veto.

After Democrats failed in two attempts to get Congress to override his vetoes of housing bills, President Eisenhower signed a trimmed-down, billion-dollar compromise measure. It retained provisions authorizing Federal Housing Administration loan guarantees for construction of proprietary nursing homes, direct federal loans for housing for interns and nurses, and both loans and loan guarantees for housing for elderly persons.

Congress approved a four-year extension of the air pollution control program, with authorization for an annual appropriation of 5 million dollars. The House and Senate could not agree on legislation expanding the water pollution control program, which will thus continue on the present authorized scale of 50 million dollars a year.

At the President's request, Congress changed Child Health Day from May 1 to the first Monday in October each year. The change was made because May 1 also had been designated Loyalty Day.

FEDERAL EMPLOYEES' NEW HEALTH INSURANCE

Over 75% of federal employees are expected to sign up for the voluntary health insurance program approved by Congress shortly before it adjourned this year's session.

The program will get under way next July 1 with more than 4,500,000 federal workers and members of their families eligible for coverage.

The Civil Service Commission will contract with various health groups and insurance companies for basic and catastrophe hospitalization and medical care. The government will pay half the cost of the basic coverage, expected to be about $13.50 per month per family. The total annual cost to the government is estimated at about 107 million dollars.

The program, which was endorsed in principle by the American Medical Association, will also cover members of Congress and legislative, judicial, and District of Columbia employees and their families. Coverage will continue for employees retiring after next July 1 with a minimum of 12 years of federal service.

Other legislation, supported by the A. M. A. and left pending in the Senate, would extend coverage to an estimated 250,000 already retired federal workers. Prospects for passage next year appear good.

NEW PHYSICAL AND MENTAL STANDARDS FOR AIRPLANE PILOTS

The Federal Aviation Agency will put into effect Oct. 15 new rules governing the physical and mental requirements for airplane pilots and other members of flight crews.

An applicant will be disqualified if his established medical history or clinical diagnosis shows "(1) diabetes mellitus which requires insulin or other hypoglycemic drug for control, (2) myocardial infarction, or (3) angina pectoris or other evidence of coronary heart disease which the Civil Air Surgeon finds may reasonably be expected to lead to myocardial infarction."

Specific disqualifying mental or nervous conditions are listed, as follows: "A character or behavior disorder which is sufficiently severe to have repeatedly manifested itself by overt acts, a psychotic disorder, chronic alcoholism, drug addiction, epilepsy, or a disturbance of consciousness without satisfactory medical explanation of the cause."

Also disqualifying are "any other disease of the nervous system, mental abnormality, or psychoneurotic disorder which the Civil Air Surgeon finds" either renders the applicant unable safely to perform the necessary duties now or "may reasonably be expected to result" in such incapacity within two years.

No waivers of diabetes or diseases of the heart or nervous system will be permitted. However, waivers of other physical requirements will be permitted, if an applicant can prove he is capable of meeting a pilot's responsibilities in emergency as well as normal situations.

In a statement in the *Federal Register* the Federal Aviation Agency said that the new regulations incorporate practices that have been followed informally for many years.

The agency said that, in drafting the regulations, "great weight was given to the comments received from doctors and medical associations," including the American Medical Association.

"The majority of individual doctors indicated their approval," and the A. M. A. and other medical groups gave strong support, the FAA said.

The comments of the medical profession were interpreted as giving "overwhelming and authoritative support to the medical standards being adopted" in the new regulations.

The FAA has also proposed that 60 years be set as the maximum age for a pilot, but a final decision will not be reached until later. There is no age limitation now.

NUMBER OF PARALYTIC CASES OF POLIOMYELITIS DECREASES

First reports showed that the number of paralytic cases of poliomyelitis declined early in September for the first time since early summer.

A total of 291 cases, widely scattered throughout the United States, were reported for the week ended Sept. 5. This was 27 cases less than in the previous week but the Public Health Service cautioned that reports of some cases might have been delayed because of the Labor Day week-end holiday.

The newly reported cases brought to 2,791 the total of paralytic cases this year, more than twice the 1,206 cases in the same period last year, but this year's total to date was less than half the number of cases in the same period in 1955, the first year Salk vaccine became available.

During the week of Sept. 5 4,219,492 doses of vaccine were released. Manufacturers shipped 1,729,769 doses to United States communities and exported 278,158 doses. Orders were on hand for most of the unshipped vaccine.

PERSONNEL

In the final days of the recently adjourned session the Senate confirmed President Eisenhower's nominations of Major Gen. Leonard D. Heaton as U. S. Army Surgeon General with the rank of lieutenant general. Heaton, who had been Commanding General of the Army's Walter Reed Medical Center, operated on President Eisenhower there for ileitis in 1956.

Dr. Donald Roger Chadwick, a career medical officer of the Public Health Service, is secretary of the newly established Federal Radiation Council. The council named Dr. Chadwick for the post on the recommendation of Dr. George B. Kistiakowsky, President Eisenhower's special assistant for science and technology.

President Eisenhower named as new members of the Board of Regents of the National Library of Medicine Drs. Maynard K. Hine of Indianapolis, dean of Indiana University's School of Dentistry, and Warner L. Wells, assistant professor at the University of North Carolina Medical School.

American Society of Anesthesiologists, Inc., Americana Hotel, Bal Harbour, Fla., Oct. 5-9. Mr. John W. Andes, 188 W. Randolph St., Room 1101, Chicago 1, Executive Secretary.

American Society of Facial Plastic Surgery, Chicago, Oct. 15-17. Dr. Samuel M. Bloom, 123 E. 83rd St., New York 28, Secretary.

American Society of Plastic and Reconstructive Surgery, Hotel Fontainebleau, Miami Beach, Fla., Oct. 18-23. Dr. Thomas Ray Broadbent, 508 E. South Temple, Salt Lake City, General Secretary.

American Society of Tropical Medicine and Hygiene, Claypool Hotel, Indianapolis, Oct. 28-31. Dr. Rolla B. Hill, 3575 St. Gaudens Road, Miami 33, Fla., Executive Secretary.

Arizona Academy of General Practice, Hotel Valley Ho, Scottsdale, Oct. 15-17. Dr. Arthur V. Dudley Jr., 1524 N. Norton, Tucson, Ariz., Convention Chairman.

Association of Clinical Scientists, Sheraton-Park Hotel, Washington, D. C., *Oct. 10. Dr. Robert P. MacFate, 323 Northwood Rd., Riverside,* Ill., Secretary-Treasurer.

Association of Life Insurance Medical Directors of America, Hotel Statler Hilton, New York City, Oct. 21-23. Dr. Royal S. Schaaf, Prudential Insurance Co., P. O. Box 594, Newark 1, N. J., Secretary.

Association of Medical Illustrators, Seattle, Oct. 5-7. Miss Rose M. Reynolds, University of Nebraska College of Medicine, 42nd Dewey Ave., Omaha 5, Corresponding Secretary.

Central Neuropsychiatric Association, Hotel Roosevelt, New Orleans, Oct. 16-17. Dr. Ralph M. Patterson, Columbus Psychiatric Institute, 473 W. 12th Ave., Columbus 10, Ohio.

Clinical Orthopaedic Society, Memphis, Oct. Dr. Charles H. Frantz, 1810 Wealthy St., S.E., Grand Rapids 6, Mich., Secretary-Treasurer.

Congress of Neurological Surgeons, Americana Hotel, Miami, Fla., Oct. 28-31. Dr. Richard L. DeSaussure, Suite 101 B, 20 S. Dudley St., Memphis, Tenn., Secretary-Treasurer.

Delaware, Medical Society of, Oct. 14-15. Mr. Lawrence J. Morris Jr., 621 Delaware Ave., Wilmington 1, Del.

Indiana State Medical Association, Murat Temple, Indianapolis, Oct. 6-9. Mr. James A. Waggener, 1021 Hume Mansur Bldg., Indianapolis 4, Executive Secretary.

National Rehabilitation Association, Statler-Hilton Hotel, Boston, Oct. 26-28. Mr. Edward D. Callahan, 14 Court Square, Boston 8, Conference Chairman.

National Safety Congress and Exposition, Chicago, Oct. 19-23. For information write: National Safety Council 425 N. Michigan, Chicago 11.

New England Society of Allergy, Longwood Towers, Boston, Oct. 28. For information, write NESA, 300 Longwood Ave., Boston.

New Hampshire Medical Society, Equinox House, Manchester, Vt., *Oct. 1-4. Mr. Hamilton S. Putnam, 18 School St., Concord, N. H.,* Executive Secretary.

Osler Society of St. Louis City Hospital, Bellevue-Stratford and Jefferson Medical College, Philadelphia, Oct. 26-27. Dr. Jack Barrow, *110 S. Central, St. Louis 5, Secretary-Treasurer.*

Pacific Coast Obstetrical & Gynecological Society, St. Francis Hotel, San Francisco, Oct. 21-24. Dr. Donald W. de Carle, 2000 Van Ness Ave., San Francisco, Chairman.

Pacific Northwest Society of Pathologists (Fall Meeting), Gearhart, Ore., Oct. 15-17. Dr. Nelson R. Niles, U. of Oregon Med. School, Portland 1, Ore., Secretary.

Pennsylvania, Medical Society of the State of, Penn-Sheraton Hotel, Pittsburgh, Oct. 18-23. Mr. Lester H. Perry, 230 State St., Harrisburg, Pa., Executive Director.

Southern Psychiatric Association, Sheraton-Dallas Hotel, Dallas, Texas, Oct. 4-6. Dr. Richard C. Proctor, Dept. of Psychiatry, Bowman Gray School of Medicine, Winston-Salem, N. C., Secretary-Treasurer.

Tri-State Medical Assembly, Confederate Memorial Medical Center, Shreveport, La., Oct. 2-3. Dr. J. W. Wilson Jr., 940 Margaret Place, Shreveport, La., Secretary-Treasurer.

Vermont State Medical Society, Equinox House, Manchester, Oct. 1-4. Mr. *Getty Page, 128 Merchants Row,* Rutland, Vt., *Executive Secretary.*

Virginia, Medical Society of, Equinox House, Roanoke, Oct. 4-5. Mr. Robert I. Howard, 4205 Dover Rd., Richmond 21, Va.

Western Industrial Medical Association, Inc., Statler Hotel, Los *Angeles, Oct. 2-3. Dr. A. C. Remington, 9851 Sepulveda Blvd.,* Los Angeles 45, Secretary.

Western Orthopedic Association, Brown Palace Hotel, Denver, Oct. 18-22. Vi Mathiesen, 354 21st St., Oakland 12, Calif., Executive Secretary.

November

Academy of Medicine of Cleveland Seminar on Recent Advances in Diagnosis and Therapy of Malignant Disease, Cleveland, Nov. 1-19. Dr. H. S. Van Ordstrand, 2009 Adelbert Rd., Cleveland 6, Chairman.

American Academy for Cerebral Palsy, Statler Hilton Hotel, Los Angeles, Nov. 30-Dec. 2. Dr. Glidden L. Brooks, Brown University, Providence 12, R. I., Secretary.

American Association of Blood Banks, Edgewater Beach Hotel, Chicago, Nov. 4-7. Dr. John B. Alsever, Southwest Blood Banks, 1211 W. Washington St., Phoenix, Ariz., Secretary.

American Clinical and Climatological Association, The Homestead, Hot Springs, Va., Nov. 2-4. *Dr. F. Tremaint Billings, 420 Medical Arts* Bldg., Nashville, Tenn., Secretary.

American College of Chest Physicians, Dallas, Texas, Nov. 29-30. Mr. Murray Kornfeld, 112 E. Chestnut St., Chicago 11, Executive *Secretary.*

American Fracture Association, Roosevelt Hotel, New Orleans, Nov. 1-5. Dr. H. W. Wellmerling, 610 Griesheim Bldg., Bloomington, Ill., Executive Secretary.

American Medical Women's Association, Arlington Hotel, Hot Springs, Ark., Nov. 12-15. Mrs. Lillian T. Majally, 1790 Broadway, New York 19, Executive Secretary.

Association of American Medical Colleges, Edgewater Beach Hotel, Chicago, Nov. 2-4. Dr. Ward Darley, 2530 Ridge Ave., Evanston, Ill., Executive Director.

Association of Military Surgeons of the United States, Mayflower Hotel, Washington, D. C., Nov. 8-11. Lt. Col. George M. Beam, AUS, Ret., Suite 718, New Medical Bldg., 1726 Eye St., N. W., Washington 6, D. C., Executive Secretary.

Central Society for Clinical Research, Drake Hotel, Chicago, Nov. 6-7. Dr. Austin S. Weisberger, 2065 Adelbert Rd., Cleveland 6, Secretary.

MENTAL ILLNESS, REVERSIBLE AND IRREVERSIBLE

Franklin G. Ebaugh, M.D., Denver

Emotionally disturbed patients commonly progress along a path that begins with nebulous complaints in doctors' offices and continues with accidents, delinquencies, troubles with family and police, unemployment, alcoholism, and either suicide or institutional adjustment. The path can be reversed, but such reversal involves immensely difficult personal and social problems. The logical approach would be to attack emotional disturbance at its point and time of origin. If it cannot be stopped there, systematic efforts must be made to reverse the trend at whatever stage may have been reached. In any case, the progress of the patient toward prolonged or permanent institutional life should be halted if possible, and he should work toward the reestablishment of a healthy, dynamic relation to the community.

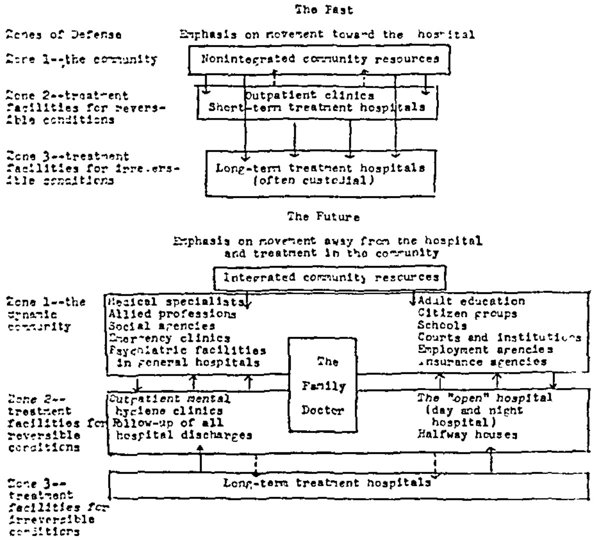
IN THE midst of the enlightened clamor in the lay press today about the staggering human and monetary cost of mental illness in the United States, I become increasingly concerned about what I choose to term the "dead zone" in the mental illness program—the vast area of untapped resources where, as in the eye of the hurricane, the sound does not penetrate and the spark of action remains unstruck. In my opinion it is only by restoring life to this "dead zone" that we may reverse the previously irreversible, both the course of a patient's mental illness itself and the limitations of society's attitudes toward it. It is only partly lack of skill, motivation, manpower, and money which has made us unable, thus far, to form an unyielding battle line between the emotionally ill citizen of the community and the "point of no return," which too often means a life completed without hope in a hospital for long-term treatment of the mentally ill.

It is important not only for the lay public but also for the general and specialized medical practitioner to adopt an extended philosophy in dealing with the increasing loss of human resources as a result of crowding persons into inadequately staffed hospitals for the mentally ill. There is no question that more and better trained personnel, more money, and better equipment for the long-term treatment facility represent part of the issue; this remains one line of attack on mental illness and, like any emergency measure, these things are essential today. We must start where we are; we cannot wish away or disown our history, which in any case reflects a steady line of progress of which we may be proud.

Nevertheless, if we are to accept the challenge of our better knowledge and therapeutic methods, we must face, courageously and clearly, the fact that, in the massive proportions in which it exists today, the long-term treatment facility or custodial hospital is a monument to failure. This is true just as surely as the remaining hospitals for treatment of advanced tuberculosis in the United States are monuments to past social and medical failure. The plague of tuberculosis has submitted to systematic preventive attack at the dynamic community level, and the "mopping up process" is well under way. We could do no better than to take a leaf from this particular history book, in attacking emotional disturbance at its point and time of origin. Perhaps, then, the overflowing mental hospital will also fade from its place of prominence on our national scene.

Cycle of Irreversibility

Toward this end, consider the essentials of advance lines of defense in terms of the reversibility or irreversibility of a patient's mental illness. The cycle of irreversibility is well known to many. It begins with the hiatus between the onset of disabling mental illness and appropriate treatment. This hiatus is too often filled with repeated failure experiences for the patient, panic leading to the conviction that he cannot be helped, increasing disruption of those environmental relationships which mean security and self-esteem to him, and often the total loss of a life role to which he may return when he has improved. It is often during this period that the patient trails from doctor to doctor with nebulous hypochondriacal and psychosomatic complaints, through the divorce and police courts, through the employment agencies, down the path of alcoholism, or into other equally personally and socially destructive adjustments. Even should he or his friends understand the implications of his difficulties, help is frequently unavailable at the community level without disruption of his entire way of life. He is in the "dead zone," where the resources are all around him, tantalizingly, and where professional people are eager to help; yet help is piecemeal, without continuity, or unavailing, costly, and wasteful.



The Past
Zones of Defense
Emphasis on movement toward the hospital
Zone 1--the community
Nonintegrated community resources
Zone 2--treatment facilities for reversible conditions
Outpatient clinics
Short-term treatment hospitals
Zone 3--treatment facilities for irreversible conditions
Long-term treatment hospitals (often custodial)
The Future
Emphasis on movement away from the hospital and treatment in the community
Integrated community resources
Zone 1--the dynamic community
Medical specialists
Allied professions
Social agencies
Emergency clinics
Psychiatric facilities in general hospitals
Adult education
Citizen groups
Schools
Courts and institutions
Employment agencies
Insurance agencies
The Family Doctor
Zone 2--treatment facilities for reversible conditions
Outpatient mental hygiene clinics
Follow-up of all hospital discharges
The "open" hospital (day and night hospital)
Halfway houses
Zone 3--treatment facilities for irreversible conditions
Long-term treatment hospitals

Schema of approach to mental health problems.

Much later, the patient may reach an intensive-treatment facility, where efforts in his behalf are better integrated and where, if he is fortunate, his illness may still prove reversible. There is, however, the long road back, the rebuilding of a shattered life structure, the problem of resisting firmly imprinted neurotic habits of adjustment, and the need to "live down" what ever has been antisocial in his illness. Furthermore, he must make the change from the hospital to a full functioning life in the environment in one big jump, because there are too few operating plans for progressive rehabilitation. Perhaps the first stumbling block returns him to the hospital, and this time he cannot "come back"; he has started on the irreversible path to the long-term treatment facility or custodial institution, where he may remain the rest of his life.

Granted, this story is told in too many absolutes; it is exaggerated for impact. Yet it provides a paradigm for the problem of community treatment of mental illness, and it is true in an astounding number of cases.

Reversibility and Zones of Defense

Reversibility, on the other hand, requires a radical change in those past and present trends which define the hospital as the major zone of defense; even the intensive-treatment facility should be relegated to a position of last resort, prior to semipermanent institutionalization. Reversibility is movement away from the hospital, treatment of personality disorders in the midst of the dynamic forces which produce them, at a community level. In this context, the family doctor becomes the central focus. Through him the communication takes place; around him, other treatment resources are organized, with primary emphasis on outpatient clinics, psychiatric facilities in general hospitals, and "open" hospitals for psychiatric patients who benefit from partial but not total participation in the community. The family doctor necessarily becomes chairman of the board, for he retains the closest contact with the community. In this context, and in return for this additional responsibility, he has for the first time the resources to fulfill emotional needs in his patients which he has long recognized. Such a program lifts a punishing load of frustration from the shoulders of the busy general physician.

The schematic presentation in the figure compares the zones of defense against mental illness as they have existed in the past and as they should exist in the future, in the context of treatment of patients within the community. The shift will include changes in quality which will be discussed shortly, but the emphasis is also on quantity—the realignment of our strength at the first and second zones rather than at the third zone of defense.

The magnitude of the problem may be realized when one considers that, in the United States on an average day, the number of persons hospitalized with psychiatric disorders equals the number of those hospitalized with all other illnesses combined. Further, of these mental illnesses, more than half represent nonorganic schizophrenias (there is an honest difference of opinion in this area), depressive states, or severe psychoneuroses. In addition to this there are untold ambulatory cases, in private care or receiving no treatment whatever. The probably conservative estimate that one of 12 infants will suffer from mental disease in the later course of his life and that one of every 16 Americans is now mentally ill does not consider the psychological components in psychosomatic ailments (asthma, allergies, migraine, rhinitis, urticaria, neurodermatitis, ulcerative colitis, peptic ulcer, nonglandular obesity, essential hypertension, etc.), nor does it include the 20,000 suicides each year. Accident-proneness, delinquency, crime, marital discord, and divorce, as well as such problems as impotence and frigidity, raise the estimate to astronomical proportions. Further, there are countless cases of minor compulsions, private phobias, and transient hysteriform simulations of certain diseases.

One must then consider the pain which the individual with emotional disturbance sustains and the effect of this on his family and associates, on his career and his aspirations, and on his socioeconomic status. The ramifications are of massive social significance.

Data from the National Committee Against Mental Illness (1957) estimate the annual cost of mental illness to be more than 4 billion dollars per year, or an average of $1,100 per patient. This figure includes loss in patient earnings and in federal income-tax revenue, maintenance of Veterans Administration patients in public mental hospitals, compensation and pension payments to veterans, construction and renovation of state mental hospital facilities, hospital care for mentally defective and epileptic patients, and public assistance for mentally ill and defective persons.

Major Lines of Defense

Let us return now to consideration of our major lines of defense against this staggering national liability: (1) the community approach (the most neglected for a number of years), (2) the intermediate or "reversible treatment" approach (the outpatient clinic, the "open" hospital, and the halfway house), and (3) the long-term hospitalization or "irreversible treatment" approach.

My contention that the first two zones of defense are in need of further improvement (signs of such improvement are already all around us) and that the large mental hospital programs should be deemphasized is not new. In the early 1850's, members of the American Psychiatric Association, then known as the Association of Superintendents of American Asylums for the Insane, stressed the desirability of small hospitals, with a capacity not greater than 250 patients. That their recommendations had little support is evidenced by our large mental hospitals today. Now again, in this radically changing world, the applicability of the "bricks and mortar" approach (larger and larger hospitals) should be questioned.

Another problem confronting mental hospitals is that they cannot be staffed, not only because professional personnel are not available and remuneration is lower but also because some hospitals are located in areas which offer the least desirable living conditions. This is particularly true of some of our VA facilities for patients with chronic neuropsychiatric conditions. Only 15 states have more than 50% of the total number of physicians needed to staff their mental institutions. On the national average the supply of registered nurses is calculated to be only 19.4% adequate; of social workers, 36.4%; and of psychologists, 65%. Even the number of attendants, the least highly trained of the necessary ward personnel, is only 80% of that desired. Small hospitals should be constructed, closer to university medical schools and more populated areas. Not only does this assure that more interest will be accorded to the long-term patient and that hospital staffing will be better but it also derives the multiple benefits of treating the patient "close to home."

In the intermediate area, which I have chosen to label the zone of reversible treatment, at least two improvements are desirable: the number of mental hygiene clinics should be increased and improved facilities for treating emergent psychiatric problems should be developed.

It is estimated that there should be at least one full-time mental health clinic for every 50,000 persons, a total of about 3,300 clinics for the United States. At present there are only about 1,200 such clinics in the entire country, and about half of these give only part-time service. One state has no clinic. Some states have only one or at most two. More than 50% of the mental hygiene clinics are located in the Northeast, which has only 25% of the population. Furthermore, many of the existing clinics are not properly spaced to accommodate the needs of surrounding areas.

Policy changes in already functioning clinics, with screening of emergent cases and perhaps also intensified methods of therapy, would increase efficiency in handling problems. As frequently happens now, waiting lists of applications for treatment extend from six months to two years into the future; by the time applicants can receive help, a large percentage of problems will have resolved themselves, perhaps by bypassing the clinic and proceeding into the third zone, the long-term treatment facility. Where is the immediate help for the acutely ill, perhaps suicidal patient? Many times, as shown[1] at the Bronx Municipal Hospital emergency psychiatric clinic, immediate diagnosis and therapy can prevent a patient from decompensating further and can obviate long-term hospitalization. The Bronx emergency clinic represents a new and seemingly highly successful approach, which might well be duplicated in other communities. In fact this concept might be considered a cornerstone of the first zone, or community approach.

Recently, some definite advances have been made in the community zone of approach to emotional problems. Psychiatric wards are being opened in general hospitals, and in some areas the emotionally ill are not kept separate from the medical and surgical patients. This approach has at least two excellent effects: 1. It improves the psychiatric patient's state of mind about his own illness, while proving to others that the patient is not a wild, "crazy," maniacal person; thus, it helps dispel this destructive misconception from the public mind. 2. Physicians who are not psychiatrists may assimilate more specialized knowledge about approaching and managing the emotionally ill patient. Today there are still too many physicians who do not wish to understand and accept mental illness in their patients. In this regard, I suspect that what superficially appears to be prejudice is more accurately to be understood as an adaptive reaction to the frustration of attempting to deal with emotional problems in patients without the proper facilities. The only solution for the general physician has been to ignore and deny the issue. Closer cooperation and day-to-day rapport will help to erase much of the mystery and misunderstanding in the relationships between nonpsychiatrists and "head-shrinkers." We work with the same clay.

Other experimental programs at the community level have also been successful thus far. The day and night hospitals have demonstrated that some patients can be gainfully employed in occupations in which they achieve satisfaction and can play a normal role in the work area, although they may not yet be ready to return to family relationships which involve conflict situations.

Halfway houses, for the patient released from a large institution, help him to find himself again in society and to gain confidence in his ability to respond and function adequately, without the full impact of the pressures of everyday life. Facilities of this kind, in particular, could be expanded in many communities at minimal cost.

Comment

Throughout this paper, I trust, I have expressed my own firm conviction that it is possible to manage our mental health problem with the serenity and consistency we achieve in many other areas, to accept it as an integrated part of our national life rather than relegating it to the isolated status of something we sporadically and helplessly worry about. The direction in which the solutions lie is clear, and the diagrams are very nearly complete. For many patients, until very recently, the large and often custodial hospital was a dead end, spelling the waste of 20 to 50 years of remaining life span. Now, there is a more dynamic approach to therapy, and with the aid of psychopharmacological agents, utilization of the dynamic community milieu, and immediate treatment near home, fewer persons will be lost to society. At one time, the mental hospital was a humane and enlightened concept in the treatment of mental illness, infinitely preferable to a prejudiced and destructive outside environment. Time and pioneering effort have altered this situation, until the dynamic community has become a vast untapped therapeutic resource. The moment has come, therefore, to reverse the trend of movement toward the hospital and encourage movement away from the hospital, to reverse what was previously irreversible.

THE SURGICAL APPROACH TO HIATAL HERNIA IN THE ELDERLY PATIENT.—Equal anatomic restoration of the crura and the cardioesophageal angle can be accomplished from either above or below the diaphragm. The advantage of the abdominal procedure is that it may lead to the recognition and correction of other intraabdominal lesions. Because most elderly patients have decreased pulmonary function, the abdominal procedure is better tolerated. Intercostal neuralgia is an occasional sequel of the thoracic procedure. For these reasons an abdominal approach is usually advisable in the elderly patient.—C. C. Craighead, M.D., and R. C. Reyes, M.D., The Surgical Approach to Hiatal Hernia in the Patient Past 60 Years of Age, *The American Journal of Gastroenterology,* July, 1959.

SWEAT PATTERNS AND SKIN TEMPERATURES IN PATIENTS WITH BRAIN AND SPINAL CORD LESIONS

Grace M. Roth, Ph.D., Hans D. Trelle, M.D., Joseph G. Rushton, M.D.
and
Earl C. Elkins, M.D., Rochester, Minn.

The status of the sympathetic nervous system, as manifested in sweat production and skin temperature, was studied in 30 patients with various lesions of the brain and spinal cord. In group 1, consisting of six poliomyelitis patients, the ability to sweat and to make vasomotor adjustments was found normal with few exceptions. In group 2, consisting of six patients with brain disease, two showed abnormal patterns of skin temperature and/or sweating. In group 3, consisting of ten patients with spinal cord compression below the level of the eighth cervical segment (C-8), both skin temperature and sweating showed numerous abnormal patterns. In group 4, consisting of eight males with spinal cord compression at or above C-8, anhidrosis was extensive in one and complete in all the others; only two had normal patterns of skin temperature. The distribution of the autonomic fibers that control sweating does not coincide with that of the fibers that control vasomotor activity.

Kottke and Stillwell,[1] Abramson,[2] and Stenpart[3] have reported that hyperactivity of the sympathetic nervous system after anterior poliomyelitis may cause abnormal vasoconstriction in the feet and legs, resulting in coldness, cyanosis, sweating, and pain when the patient is in a cold environment. This reaction to a cold environment had caused definite disability to the patients but was relieved by depression of sympathetic activity induced with the use of dehydrogenated ergot, alkaloids, or tolazoline (Priscoline) hydrochloride. The question arose of whether these symptoms disappeared or were still present after many years, and it was decided to investigate this problem further.

In addition another study[4] had reported that hypofunction of the sympathetic nervous system occurred after unilateral as well as bilateral anterolateral chordotomy. Vasomotor and sudomotor function may be dissociated by lesions in the anterolateral quadrant of the spinal cord during intractable pain. Also, the autonomic fibers are more widely distributed in the anterolateral column of the spinal cord than has been thought. Therefore the present investigation was begun to study the vasomotor disturbances of the autonomic pathways in the spinal cord and brain of patients after trauma.

Material and Methods

Four groups of patients were studied. Group 1 consisted of six patients with residual anterior poliomyelitis which had been present from 14 months to 36 years. Group 2 consisted of six patients with various diseases of the brain, with associated paresis or paralysis due to burns, tumors, fractures, or cerebral vascular accidents. In group 3 were 10 patients with compression of the spinal cord below the eighth cervical segment, and in group 4 were 8 patients who had compression of the cord at or above the level of the eighth cervical segment.

Skin Temperatures.—The basal metabolic rates and the skin temperatures of the fingers and toes were determined in each patient.

Before the tests the subjects fasted for 15 hours. During the tests they wore lightweight short pajamas and lay supine on comfortable beds. Data were obtained in a room in which the constant temperature was 25.5 C (78 F) and the relative humidity 40%. The temperatures of the plantar surface of the first and third toes of both feet and the volar side of the distal phalanges of the first and third fingers were determined by means of copper-constantin thermocouples. The observations were made at intervals of 10 minutes for one to two hours.

In the normal person there is a gradient of skin temperature from the head to the feet, with the lowest skin temperatures in the toes. It has been shown too that the skin temperature of the toes will depend on the initial basal heat or the basal metabolic rate. This gradient of skin temperature is present constantly, although it is less when the basal metabolic rate is particularly high. Reversal of this gradient between the skin temperatures of the toes and the fingers was considered to exist when the average temperature of the toes exceeded the average temperature of the fingers by 1.5 C (2.7 F) or more in the room at a temperature of 25.5 C. Such a reversal was first observed after surgical removal of sympathetic ganglions.

In order to evaluate peripheral vasoconstrictor activity a number of the patients were transferred to a cold room where the temperature was main-

tained at 20 C (68 F). They were exposed to this temperature for 30 to 40 minutes. Impairment of vasoconstriction was indicated when the skin temperatures decreased less than 2.5 C (4.5 F).

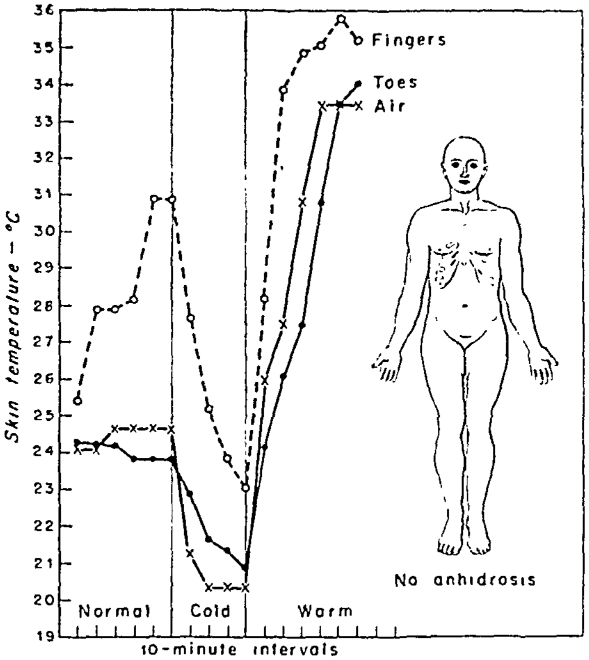

Fig. 1.—Effect of changes of environmental temperature on skin temperature of fingers and toes of patient with anterior poliomyelitis. Complete sweating occurred during thermoregulatory test.

Sweating Test.—The cobalt chloride method of determining the region of anhidrosis was used. Cobalt chloride in a saturated alcoholic solution is deep blue but turns to bright pink on addition of water. The alcoholic solution was striped over the area to be examined; an aluminum heating cabinet large enough to cover the entire body except the head, containing a series of incandescent light bulbs which maintain a temperature of about 140 F, was placed over the patient; and in 10 minutes, or whenever sweating occurred, the stripes became a bright pink. The change in color of the stripes indicated the varying degrees of sweating with considerable accuracy. Lack of change in color indicated anhidrosis.

Results

Group 1: Patients with Residual Anterior Poliomyelitis.—The average age of the six patients (two women and four men) with residual anterior poliomyelitis in group 1 was 31 years, with a range from 13 to 54 years. The basal metabolic rates ranged from —19 to +3%.

The normal pattern of skin temperatures with the fingers higher than the toes was observed in all except one patient, in whom transplantation of the biceps femoris had been done. Normal vasoconstriction occurred in the cold room and normal vasodilatation in the hot room (fig. 1).

Sweating occurred over the entire body in all the patients except one. The exception, a 54-year-old woman who had had poliomyelitis 36 years previously, was found to sweat only on the arms and the back of the legs. However, the pattern of skin temperatures of her fingers and toes was not changed significantly from the normal in spite of the anhidrosis (fig. 2).

Group 2: Various Diseases of the Brain.—The average age of six patients (one woman and five men) with brain disease was 40 years, with a range from 19 to 59 years.

The normal pattern of skin temperatures was observed in all but two cases. One patient, aged 19 years, who had right-sided spastic hemiplegia and partial aphasia showed some evidence of impairment of the vasoconstrictor fibers in the fingers of both hands, as the skin temperature of the fingers of the right hand decreased only 1.7 C (3 F) in the cold room and that of the fingers of the left hand did not decrease. More important was the fact that sweating occurred except on the lateral portion of the left thigh and the lateral aspect of the right calf. The second patient, aged 43 years, had had a skull fracture that involved both sides of the parietal and frontal regions, with subsequent left-sided hemiplegia. Although he had a normal pattern of sweating, there was evidence of slight impairment of the vasoconstrictor fibers of the left toes and fingers.

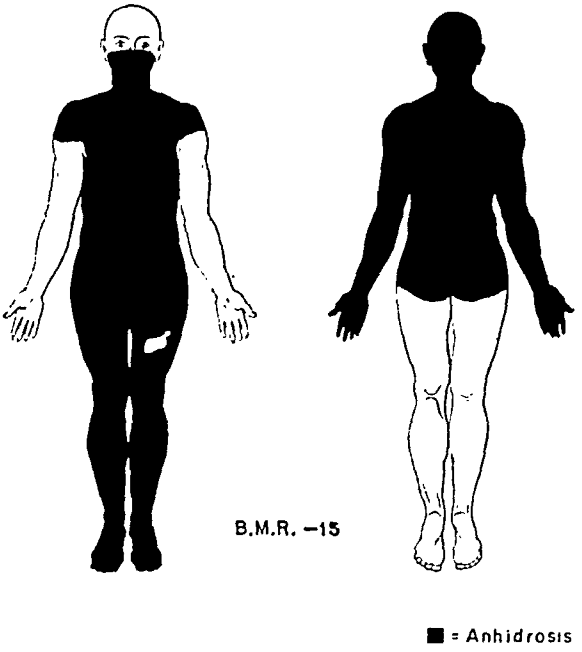

Fig. 2.—Anhidrosis in patient 36 years after anterior poliomyelitis with no reversal of skin temperature of toes (hands, 24.8 and 24.6 C [76.6 and 76.3 F], toes, 25.2 C [77.4 F]).

Group 3: Compression of the Spinal Cord Below the Level of the Eighth Cervical Segment.—The ages of 10 patients (3 women and 7 men) with spinal cord compression below the level of the eighth cervical segment averaged 29 years and ranged from 19 to 56 years. They had varied patterns of both skin temperatures and sweating. Some of these variations were thought to be due to subsequent surgical procedures such as decompression, laminectomy, anterolateral chordotomy, and rhizotomy (table 1).

In three patients (cases 1, 2, and 3) the pattern of the skin temperatures was normal, although one patient had no areas of anhidrosis, the second had anhidrosis from the level of the umbilicus down on the right and from the midthigh down on the left, and the third had anhidrosis of both arms, with only slight sweating on the lateral aspect of the chest. Both a laminectomy and a rhizotomy had been done on the second patient. The third patient had had a fracture of the neck of the first rib.

In four patients in this group a reversal of the skin temperature of the toes occurred; it was associated with anhidrosis on the right foot in two of the patients (cases 4 and 5) and with anhidrosis from the level of the umbilicus down in the other two (cases 6 and 7) (fig. 3).

TABLE 1.—*Data from Patients with Traumatic Lesions of the Spinal Cord Below the Eighth Cervical Segment*

		Skin Temperature						
			Decrease in Cold Room, C					
			Toes		Fingers			
Case	Age, Yr. and Sex	Pattern	R	L	R	L	Anhidrosis	Level and Type of Injury
1	21, M	Normal	5.6	6.3	3.9	3.3	None	T-11, laminectomy
	23, M		3.4	3.6	1.9	2.5	None	
2	56, M	Normal	4.3	5.3	3.3	6.5	Umbilicus down on right, mid thigh down on left	T-3 to T-5, laminectomy; T-4 and T-5, rhizotomy
3	27, M	Normal	4.6	2.8	4.1	3.0	Slight, lateral aspect of chest, both arms	T-11, fracture of neck of first rib; T-10 to T-12, bilateral laminectomy
4	19, F	Reversal on right foot	1.6	5.3	4.7	5.5	Right foot	T-10 to L-1, laminectomy
5	22, M	Reversal	1.8	1.4	2.6	4.0	Right foot	T-5, anterolateral chordotomy
6	35, M	Reversal	1.1	2.1	3.5	3.8	Umbilicus down	T-6, laminectomy
7	30, M	Reversal	1.2	1.2	3.4	4.5	Umbilicus down	T-4, complete transection of spinal cord
8	46, M	Impairment of vasoconstrictor fibers of feet and hands	2.2	2.5	1.7	1.0	T-2 down, hands distal to wrist	T-2, fracture of body and lamina; cord two-thirds lacerated
9	17, M	Impairment of vasoconstrictor fibers of feet and hands	1.3	2.2	0.4	1.6	T-3 down	C-8 to T-1, incomplete transection of spinal cord
10	33, F	Impairment of vasoconstrictor fibers of right hand	6.7	5.5	1.6	4.2	Right arm, hand, foot; left arm, foot, and lateral aspect of left leg	T-1 and T-2, myelitis; laminectomy; right anterolateral chordotomy

In two patients evidence of impairment of the vasoconstrictor fibers of the feet and hands was noted, with anhidrosis from the second and third thoracic segments respectively. There was also evidence of impairment of the vasoconstrictor fibers of the right hand in one patient, with anhidrosis of the right arm and hand, left arm, both feet, and the lateral aspect of the left leg. This patient had undergone a right anterolateral chordotomy.

Group 4: Compression of the Cord At or Above the Level of the Eighth Cervical Segment.—The ages of the eight males with spinal cord compression at or above the level of the eighth cervical segment averaged 22 years and ranged from 6 to 44 years (table 2). Two of these patients had normal patterns of skin temperatures with complete anhidrosis (fig. 4, *left*). The rest had impairment of the vasoconstrictor fibers either of the feet or the hands or both, with reversal of the skin temperatures of the toes in only one patient. Complete anhidrosis was present in all except one patient (case 18); this patient had anhidrosis except on the left side of the face and neck and the left shoulder and arm (fig. 4, *right*). This patient had a reversal of the skin temperatures of the left toes and impairment of the vasoconstrictor fibers of the right hand but not of the left.

Comment

The patients with residual anterior poliomyelitis had normal vasoconstriction and dilatation, and complete sweating occurred in all of these patients except the one who had been paralyzed for 36 years and had not had any operations. However, no vasoconstrictor impairment was present in this patient. Apparently after a considerable period of time the hyperactivity of the sympathetic nervous system subsides.

In patients with various brain injuries there was a dissociation between the vasoconstrictor and the sweating fibers, since impairment of the vasoconstrictor fibers was evident in association with sweating over the entire body.

In the third group, composed of patients with injuries to the spinal cord below the level of the eighth cervical segment, only one patient had a normal sweating pattern; the rest had partial sweating patterns which could be correlated to the injury and the subsequent surgical procedures. The evidence of impairment of the vasoconstrictor fibers and the anhidrotic pattern were, in all but one patient, of the usual type; that is, anhidrosis of the feet with reversal of the skin temperature of the toes. The one exception (case 2) had a normal skin temperature pattern and anhidrosis from the level of the umbilicus down on the right and the midthigh down on the left. Thus damage of the sweating fibers and not of the vasoconstrictor fibers was evident.

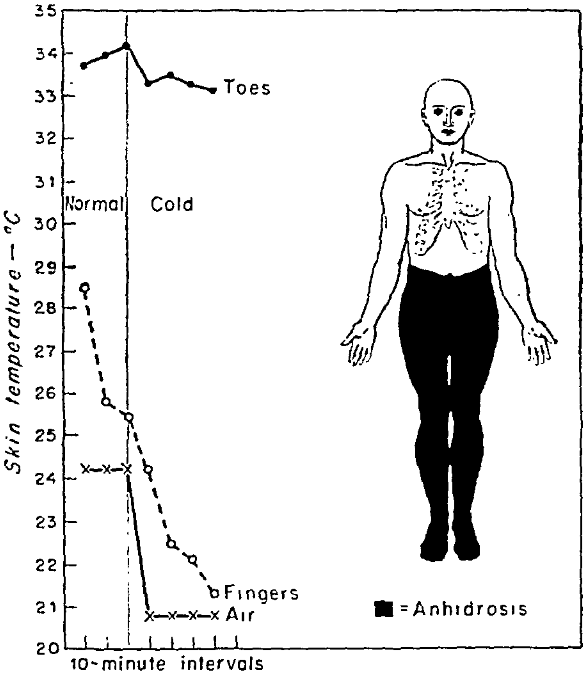

Fig. 3 (case 7).—Reversal of skin temperature of fingers and toes and decrease of only 1 C in toes and 4 C in fingers in cold room, after transection of spinal cord at fourth thoracic segment. Anhidrosis extended from level of umbilicus down.

* All patients had complete anhidrosis except case 18, who sweated on the left side of the face and neck and the left shoulder, arm, and hand.

In the fourth group all of the patients but one had complete anhidrosis over the body, and the mouth temperature rose 2 F (1.1 C) in 10 to 12 minutes while they were under the "baker." In the one exception anhidrosis was complete over the body except for the left side of the head, neck, shoulder, arm, and hand, and the skin temperatures of this extremity decreased 8.5 C (15.3 F) in the cold room. This correlation of sweating and vaso-

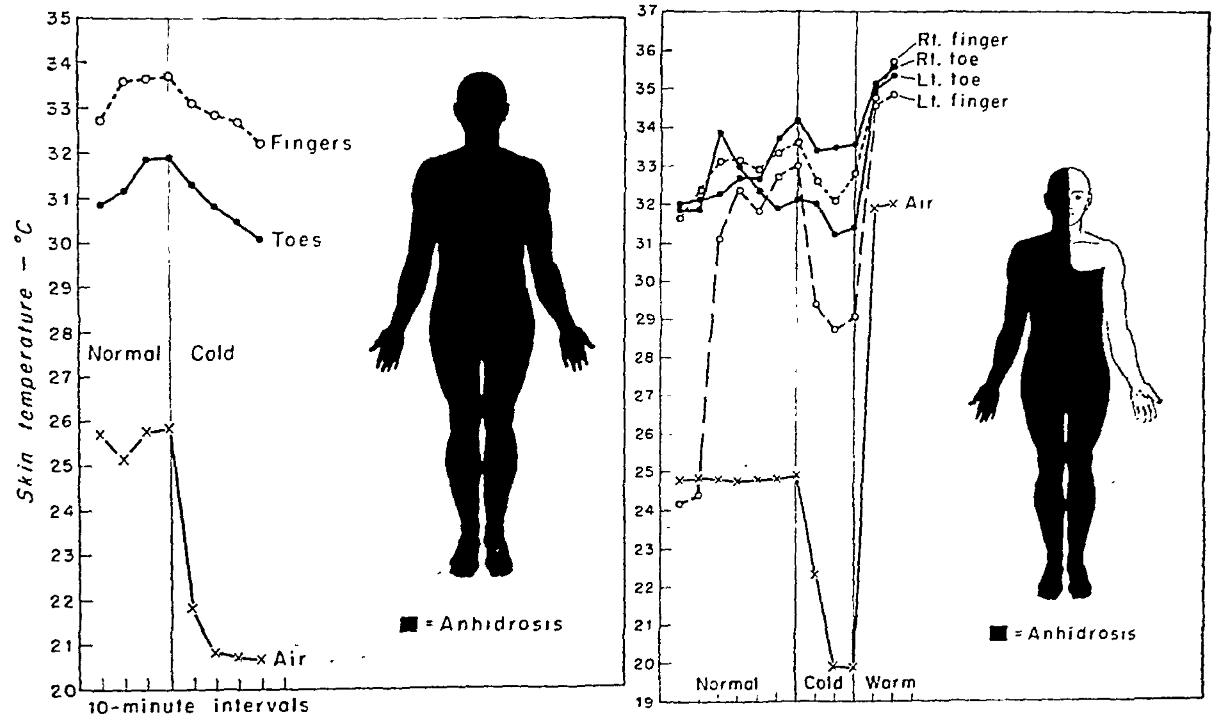

Fig. 4.—*Left* (case 11), normal pattern of skin temperatures, with decrease of 1.3 C (2.3 F) in fingers and 1.8 C (3.2 F) in toes in cold room, in patient with cord lesion above eighth cervical segment and complete anhidrosis. *Right* (case 18), reversal of skin temperature of toes in comparison to that of fingers on left hand where sweating occurred. Note decrease of 4.5 C (8.1 F) in fingers of left hand in cold room.

constriction was thought to be a striking example of the interdependence of sudomotor and vasoconstrictor fibers and a classic demonstration of the compensatory mechanism of the sympathetic nervous system in the regulation of body heat. It also might indicate the peripheral distribution of sudomotor and vasoconstrictor fibers relative to the thoracic outlet. It might be well to mention that these patients, because of inability to sweat, are difficult to care for; circulatory collapse may occur if they are subjected to a warm environment.

Summary

Sweating patterns and skin temperatures of 30 patients with lesions of the spinal cord and brain were determined under basal conditions at constant temperatures of 25.5 and 20 C. Complete sweating occurred in patients with residual poliomyelitis and brain injuries, and nearly complete sweating in some with spinal cord injuries below the level of the third thoracic segment. A group with spinal cord injuries below the level of the eighth cervical segment showed partial lack of sweating, which coincided partly with the level of injury and surgical procedures, while those with injuries at or above the eighth cervical segment of the cord had complete lack of sweating.

In some of the patients with spinal cord injuries the vasoconstrictor fibers but not the sweating fibers were damaged; this seems to indicate a variation in the distribution of these fibers in the spinal cord.

PREVOCATIONAL EVALUATION AND REHABILITATION IN A GENERAL HOSPITAL

Arthur L. Watkins, M.D., Boston

The nonprofessional services of a hospital were found to provide a rich variety of work situations for use in a rehabilitation program. Of 44 consecutive patients who started this program, 41 completed it and 31 were successfully rehabilitated, even though an average of 23 months had elapsed since the initial injury. The setting was an acute general hospital. Three cases are described to illustrate the feasibility of using the hospital barber shop, accounting department, pharmacy, and similar facilities to test and restore the patient's occupational potentialities.

The return of the seriously injured workman to employment is an obvious goal for any rehabilitation center. All too often this goal is not achieved. For example, in the Commonwealth of Massachusetts a law has been passed which makes it mandatory for workmen's compensation insurance carriers to report all cases of patients who are not back at work six months after the injury. These reports go to the Industrial Accident Rehabilitation Board, which reviews the case histories and refers the patient to a rehabilitation facility for further evaluation and treatment. This legislation is not based on any lack of proper medical or surgical treatment which is readily available to the injured workman, but, rather, to the fact that in spite of excellent medical and surgical care all too often the injured workman does not return to employment. The rehabilitation of this group of patients is a real challenge to the physiatrist. The purpose of the presentation is to record a method of prevocational evaluation and work therapy as set up in an acute general hospital rehabilitation facility. Forty-four consecutive cases were selected for this study, representing all the workmen's compensation cases seen and evaluated, vocationally, during recent years at the Bay State Medical Rehabilitation Clinic. All patients were referred to some nonprofessional service department of the hospital for a work therapy program, which will be described.

Assistant Clinical Professor of Medicine, Harvard Medical School; Chief, Physical Medicine Department, Massachusetts General Hospital; and Medical Director, Bay State Medical Rehabilitation Clinic.

Chairman's address, read before the Section on Physical Medicine at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 9, 1959.

Method of Evaluation

An injured workman who has not returned to work because of an injury believes that he needs treatment and usually is not completely satisfied, in some way, with the result of medical therapy. For this reason, rehabilitation, I believe, is more apt to be successful if a physician directs the program and is the leader of the rehabilitation team.

It has often been said that a rehabilitation center should be separated from a general hospital for psychological reasons. We have deliberately chosen an acute hospital, however, with all its facilities for diagnosis and treatment readily available. At the same time, we have utilized actual work situations in the hospital for prevocational testing and work tolerance production.

Rehabilitation Team

In our program we have as the leader a physiatrist who provides the medical evaluation, with consultants as needed. He also directs the therapeutic program in all stages. A coordinator is necessary to take care of administrative details, make arrangements with third parties, and see that the team works together and that reports are sent out. Other members include physical therapists, social workers, and a clinical psychologist who conducts aptitude, interest, and other psychological tests. A psychiatrist acts as a consultant and discusses all cases with the team. An occupational therapist directs the hospital prevocational and work therapy program. A vocational counselor is responsible for establishing the vocational goals and the actual placement in jobs.

Hospital Work Therapy Program

At the Massachusetts General Hospital, as at any general hospital, many nonprofessional services are necessary for running the hospital (table 1). Our occupational therapist has established a cooperative relation with the foremen of the various nonprofessional services. The foreman is instructed in the placement of an injured workman under treatment in his department for purposes of evaluation of his abilities and interests and aptitude for that particular type of work and, also, for the purpose of establishing the patient's work tolerance. In the beginning, forms were utilized for evaluation by the department head; but, in the course of time, these have been discarded as unnecessary except for indoctrination of new employees. The departments are not used for the purpose of developing vocational skills or for production of work. The placement is used to develop, gradually, an eight-hour working tolerance through actual work and to instill a real work interest.

An interesting side light has been the keen interest of the foremen in this project. For the first time, after years of service in a hospital, they have become a part of an active therapeutic program in contact with patients.

Placement in work therapy is generally accompanied by physical rehabilitation in the form of conditioning exercises. We use a progressive resistance exercise table for this purpose. This technique has the advantage of providing a measurement of strength in terms of pounds which helps to evaluate progress.

A unique feature of this work therapy program has been an evaluation in terms of the physical work requirements of the different jobs by a consultant who worked with the individual foreman and established the physical requirements of many of the jobs in the hospital. Our physiatrist, physical therapist, and occupational therapist were also trained, similarly, to establish the physical abilities of patients in this fashion.[1] This combined evaluation of physical abilities and job requirements makes it possible to place a person in a suitable work situation corresponding to his physical capacities.

Patient Data

Diagnostic Categories.—The patients who were injured at work and went through this program had a variety of injuries. Three patients were not included because of lack of follow-up. There were 12 patients (29%) with serious back injuries with or without ruptured nucleus pulposus of the intervertebral disk. Some of these had operations, including laminectomy and spinal fusions. Fourteen patients (34%) suffered fractures, of the lower extremities in 10 and of the upper in 4. Four amputees (10%) were referred, with different varieties and levels of amputation sites. Eleven patients (27%) with other injuries were included, such as crushed hands, neck sprains, three brachial plexus or nerve injuries, and one case of upper extremity thermal burns. All patients were in the employable age group. The youngest was 17 and the oldest 64 years of age; there were two females.

Table 3.—*Results for Twelve Patients with Back Injuries*

Operation	Age, Yr.	Occupation	Interval, Mo.	Hospital Work Therapy	End-result*
...	45	Truck driver	19	Plumbing	...

* Former job—4; new job—3; watchman—1; elevator operator—1; bookkeeper—1; failures—5 (truck driver, 4; laborer, 1).

Interval After Injury.—These patients represent those with severe injuries who failed to return to employment after six months. In most instances, the patients were referred to our rehabilitation clinic one to three years after the date of injury, with an occasional exception of patients referred earlier for rehabilitation by the insurance carrier when change of employment would be necessary, as, for example, in the case of the amputee. The average interval was 23 months.

Age, Yr.	Type of Injury	Previous Occupation	Hospital Work Therapy	End-result*
41	Trunk and pelvis	Laborer	Refrigeration	No job (traumatic neurosis)
39	Upper extremity laceration	Meat cutter	Butcher shop	Previous job
58	Leg crush	Truck driver	Instrument repairs	Taxi driver
25	Arm crush	Crane oiler	Barber shop	Barber school; placed as barber
26	Hand crush	Paper machine	Store	Stock clerk
61	Neck strain	Mechanic	Pharmacy	Referred for placement; no job
45	Hand crush	Roofer	Carpentry; instrument repairs; maintenance	Mechanics helper
28	Syringomyelia	Roundhouse worker	Dietary office	Business school; no placement
29	Neck strain; hysterical triplegia	Steeplejack	Refrigeration	Refrigeration repair
45	Brain, subdural	Office manager	Accounting	Business school; job
49	Burn of hands	Laborer	Elevator	Elevator operator

* Previous job—1; new job—5; vocational training—3; failure—2.

Length of Treatment.—These particular patients were all ambulatory and usually came in for daily treatments five days a week with an occasional exception of a patient for whom transportation was a difficulty and therefore treatments were less frequent. Usually, treatments were continued for at least a month, an occasional patient remaining under treatment for as long as three months; one patient continued on our program for eight months.

Occupation at Time of Injury.—A large variety of occupations were represented in this study. The list includes, for example, a farmer, a tree surgeon, a window washer, a freight handler, a truck driver, a waiter, a railroad worker, a cabinet maker, a roofer, a steeplejack, a meat cutter, a machine operator, and an office manager.

Results

Of the 41 patients who completed the evaluation and therapy described, 11 returned to the same type of work with their previous employer. Fourteen were successfully placed in a new occupation and six were set up in a vocational training program under the direction of the Massachusetts Rehabilitation Commission. Thus, 75% were successfully rehabilitated. Of the 10 who failed to return to employment, 5 had a diagnosis of a back injury and 4 had been operated on, another had a recurrence of rheumatoid arthritis preventing his return to work, one had multiple soft tissue injuries, one had a fractured wrist, and another had a new injury before returning to work. A psychiatric diagnosis precluded work for one patient. Results are given in detail in tables 2 through 5. Three illustrative cases of successful rehabilitation are given below.

Report of Cases

CASE 1 (*fractured hip*).—A 58-year-old garage mechanic suffered a fractured hip at work. He was treated with closed reduction and bed rest at an outside hospital and was able to use crutches but developed severe disabling pain in the hip. It was consequently decided that an arthroplasty should be done, with insertion of an Austin-Moore prosthesis. Convalescence from this was good and he was referred five months later for further rehabilitation therapy. At the time of referral, he was walking with a cane and driving his own car. In his prevocational evaluation it was found that he was able to do simple addition and subtraction satisfactorily but not multiplication or division. He had a three-hour standing tolerance and was referred to the hospital work therapy program. His first placement was in the pharmacy, where he seemed to have some aptitude for work with machines. He also demonstrated a full day's working tolerance sitting at work operating a foot lever. A second trial of work placement was in the accounting department, where it was found that he was cooperative and dependable. After three weeks of the work therapy program he was seen by the vocational counselor, who found employment for him in a bookkeeping capacity.

TABLE 5.—*Results for Twelve Amputees*

Age, Yr.	Type of Amputation*	Previous Occupation	Hospital Work Therapy	End-result
19	BE	Cabinet maker	Accounting	Accounting school
45	AE	Machine operator	Instrument repairs	Previous job
46	AE	Wool comber	Instrument repairs; carpentry	Watchman for previous employer
63	AK	Cement manufacturer	Instrument repairs; refrigeration	Unemployed (arthritis)

* BE = below elbow; AE = above elbow; AK = above knee.

CASE 2 (*crush of arm*).—A 23-year-old operator of a crane injured his right hand when it was drawn into the construction machinery he was oiling on June 11, 1956. He had immediate surgical care in a nearby hospital. A diagnosis was made of comminuted fractures of the radius and ulna and severe skin and tendon injuries to the forearm. In November of the same year he was referred to the Bay State Medical Rehabilitation Clinic, where he was taken out of immobilization as per his surgeon's instructions and started on physical therapy to mobilize and strengthen his stiff joints and weak muscles. He had physical therapy three times a week for one year. During the last months of treatment he was evaluated for vocational goals since there would be some definite residual lack of function of his right hand. This prevocational evaluation was done in the occupational therapy department and his studies included aptitude and interest testing and intelligence tests plus counseling by the vocational counselor. He was found to be of normal intelligence, with interests and aptitudes in the mechanical field. The patient was very much interested in becoming a barber in spite of his less than normal hand function. He was accordingly placed in the hospital barber shop and given further tests of his skills and interests; finally, he was enrolled in a barber's school under the plan of the Massachusetts Rehabilitation Commission.

In 1958, he had further surgery for removal of internal fixation, followed by some additional physical and occupational therapy to regain as much function as could be secured after this brief post-operative period. He continued with his study of barbering and was finally employed as a barber full time. He had been on the job for three weeks and was doing well at the time of the follow-up report in February, 1959.

CASE 3 (*multiple fractures*).—A 25-year-old window washer had had several severe falls in carrying out his work, the last one occurring four and one-half months prior to admission, when he received multiple fractures. In his prevocational evaluation he received aptitude, interest, and psychometric tests which indicated normal mental ability, with reasonable clerical skills. Prevocational testing included a trial in the accounting department of the hospital, where it was found that he could follow instructions well, had good work output, and was congenial with those in the department. He was able to use an electric calculator and his supervisor was satisfied with his work. In view of this, the vocational counselor enrolled him in a business school where he finished a business course. After finishing training, he was employed as a bookkeeper and earned $55 a week. In addition to this, the patient is going to night school to work for a degree in business administration, hoping after he finishes to increase his wage potential to as much as $70 a week.

Summary

A method of rehabilitating the seriously injured worker back to employment was established in an acute general hospital rehabilitation facility. The placement of patients in a work situation for prevocational evaluation and the development of work capacity formed essential elements of this program.

The nonprofessional services of a hospital provided a rich variety of work situations. The program was directed by the rehabilitation team of the general hospital center.

Of 44 consecutive referrals, on the average of 23 months post-injury, 41 injured workers completed the evaluation and work therapy program. Thirty-one (75%) of the 41 patients were successfully rehabilitated.

CHALLENGE TO THE PRIVATE PHYSICIAN IN THE EPIDEMIOLOGY OF SYPHILIS

William J. Brown, M.D., Thomas F. Sellers, M.D.
and
Evan W. Thomas, M.D., Atlanta, Ga.

Reported cases of infectious syphilis declined between the peak years of 1947 and 1954, but since 1954 the number has remained practically unchanged each year. Public health officials understand well the responsibility of the general practitioner to protect the confidence of the physician-patient relationship, as well as his reluctance to suggest that his private patient be interviewed for contacts by a third person, but such personnel have been trained to keep all information in strict confidence and to bring to the investigation the same high professional standards as apply to diagnosis and treatment. If the trend of infectious syphilis is to turn down again, physicians must report all cases to the health department and arrange to have patients interviewed for information about sexual contacts. Examples of effective cooperation along these lines are cited.

Progress against syphilis in the United States during the past 20 years has been tremendous. The control program frequently has been referred to as one of the most successful in recent public health history. Ample statistical proof of progress is evident in such long-range indexes as trends in mortality and disability due to syphilis. For example, in 1939, when the national venereal disease control program was launched, there were 14,500 deaths due to syphilis reported (11.8 per 100,000 population). In 1956, the most recent year for which complete mortality data are available, there were 3,870 deaths from syphilis reported in the nation (2.3 per 100,000). Similarly, first admissions of syphilitic psychotic patients to mental hospitals have declined from 7,800 in 1939 (5.5 per 100,000 population) to 1,663 in 1955 (1.0 per 100,000 population).

Reported cases of infectious syphilis also declined consistently and significantly between the peak year of 1947 and 1954. However, since 1954 the number of cases of infectious syphilis reported each year has remained practically unchanged.

Figure 1 shows the trend line of reported primary and secondary syphilis in the United States since 1950. Venereal disease control personnel are most concerned with this plateau at the high level of between 6,300 and 6,800 reported cases of infectious syphilis per year. The word "reported" must be emphasized, because a large number of privately treated syphilitic patients have not been reported for one reason or another. Studies show that in some areas private physicians are reporting to health authorities as little as 5% of the syphilitic patients they treat—in other areas as much as 50%. It is estimated that approximately 25% of all privately treated syphilitic patients are reported to health departments. Thus, the data plotted in figure 1, based on incomplete reporting, represent a minimum of the true syphilis attack rate in the United States. And, of course, cases of syphilis which occur but are not diagnosed in the infectious stage of the disease are not included.

Venereal disease control officers and syphilologists agree that, to reduce the incidence of infectious syphilis and return this line to a downward trend, a much higher percentage of cases of infectious syphilis must be reported, and all reported patients in the infectious stage must be interviewed for sexual contacts so that all such contacts may be found, examined, and treated if infected. If cases are not reported it is not possible for the health department to offer a trained interviewer to obtain the names of all their sexual contacts, and if this is not done the infected contacts will continue to spread the infection. Only by complete case reporting and interviewing can we attain real control of this disease and progress toward the goal of its eventual eradication.

Failure to continue the downward trend of reported early syphilis since 1954 cannot be explained by decreased public health epidemiologic activities, because these have been maintained at levels which formerly produced significant declines. Studies have shown that, since the development of slow-absorption penicillin for the treatment of syphilis, private physicians have been treating a higher proportion of infectious syphilitic patients. Furthermore, only a small percentage of these patients with early syphilis are being interviewed adequately for sexual contacts. Figure 2 shows the number of cases of infectious syphilis reported by private physicians and by clinics in the five-year period during which practically no progress has been made against re-

---

Chief, Venereal Disease Branch, Communicable Disease Center, Bureau of State Services, Public Health Service (Dr. Brown); State Health Commissioner, Georgia State Health Department (Dr. Sellers); and former professor of clinical medicine, New York University College of Medicine, and former director of Venereal Disease Services, Bellevue Hospital, New York City (Dr. Thomas).

ducing the incidence of syphilis. This chart also shows the number of patients interviewed and the number not interviewed for sexual contacts for each reporting source.

Of the 14,428 cases of infectious syphilis reported by private physicians during the five-year period only 2,400 patients (16.6% of the total number reported) were interviewed by a trained interviewer to obtain the names and addresses of contacts. Surely, many private physicians must have advised their patients to send in their spouses for examination. This is a simple procedure requiring no special effort or training. However, it is much more difficult to obtain the names of other sexual contacts who may have introduced the infection into the family group. Such interviewing requires special training and experience.

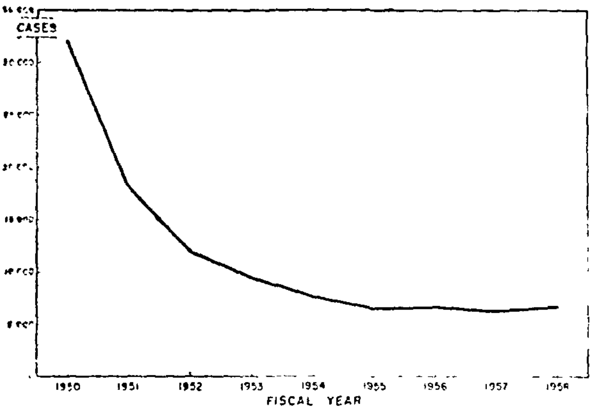

Fig. 1.—Reported cases of primary and secondary syphilis in the continental United States, 1950-1958.

In contrast to the foregoing figures, of the 19,251 patients with primary and secondary cases reported by clinics and hospitals, 16,845 (86.3%) were interviewed for contacts. Although there is still room for improvement in the interviewing of clinic and hospital patients, particularly the latter, the greatest need is for more adequate interviewing of private patients and subsequent examination of their sexual contacts. Such action would help significantly to reduce the continuing high incidence of syphilis. As discussed later, this requires close cooperation between the private physician and the health department.

Case-Finding Opportunities Lost

The epidemiology of infectious syphilis is the responsibility of health departments, but, before discussing the necessary cooperation of private physicians, let us consider what is lost by failure to obtain contacts of private patients. By applying national average indexes of case-finding productivity to the 12,028 cases of infectious syphilis reported by private physicians but not interviewed for sexual contacts, it is conservatively estimated that interviewing of these patients by trained personnel would have yielded 40,173 named contacts during the five-year period under consideration (fig. 3). Routine follow-up procedures and examination of these 40,173 contacts would have yielded 2,868 cases of primary and secondary syphilis, 1,606 cases of early latent syphilis, and 594 cases of other syphilis. It should be emphasized that these estimated undiscovered cases are minimal, since they are calculated from the base line of reported cases only.

On the brighter side there are many specific examples of excellent cooperation between private physicians and health departments in several areas where venereal disease outbreaks have occurred. For example, an extensive outbreak of syphilis occurred recently in a southwestern state. The original case of secondary syphilis was reported to the health department by a private physician who requested epidemiologic aid from the health department. A trained interviewer went to work, and a chain of infection of 79 cases of infectious syphilis was subsequently uncovered. Throughout the outbreak there was continuous communication and consultation between local physicians and the county health officer. Only through teamwork between private physicians and health department personnel was this outbreak brought under control. How many

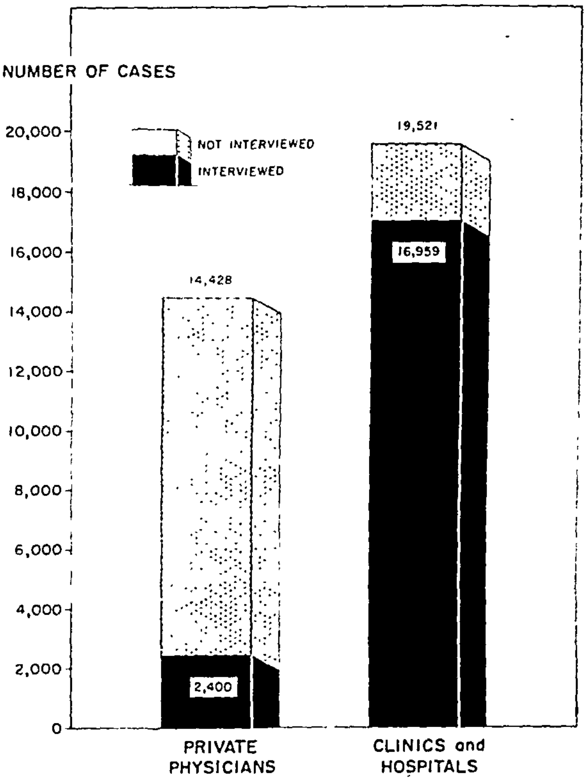

Fig. 2.—Cases of primary and secondary syphilis obtained by reporting source and interviewing sexual contacts, in the United States, *fiscal years 1954-1958.*

other equally extensive outbreaks have not been uncovered because a patient with an early case of syphilis was neither reported nor interviewed can only be guessed.

In addition to epidemiologic teamwork between private physicians and health officers in localized outbreaks of syphilis are a few statewide programs in which private physicians work side by side with the health department in a cooperative plan of control. One southern state has been particularly successful in such an effort. The first step in the program was to approach the state medical society and enlist its active participation in the control program. The reporting program was approved by the state medical society and discussed at local medical society meetings throughout the state. Simple reporting procedures were established for the convenience of physicians, and positive blood tests from public health laboratories were used to stimulate case reporting. Every physician in the state received a letter from the state health officer explaining the program and urging him to report any cases of syphilis. The splendid results of this program are shown in figure 4. More than 10 times as many cases of syphilis were reported by private physicians in the three years after the initiation in 1956 of the case-reporting program than in the previous three years. The chart refers to patients with syphilis reported in all stages of the disease.

Since the most important stages of the disease from an epidemiologic and control point of view are the primary and secondary stages, an integral part of the private physician–participation program was a sustained effort to interview all patients with these stages of disease for sexual contacts and to bring all contacts to the physician for examination. Concurrently with the general case-reporting program private physicians were especially urged to report patients with early cases of syphilis promptly and to have them interviewed for sexual contacts by a trained interviewer. In fact, each physician reporting a case of infectious syphilis was visited by a representative of the health department who offered to interview the patient. The gratifying results of this phase of the program are shown in figure 5. This chart shows that physicians who reported cases prior to the new program were already working with the health department by having most of their patients with early cases (83%) interviewed for contacts. More important, the chart shows that after the institution of the new program not only were more private physicians reporting more cases of early syphilis but the physicians were also taking an active interest in the program by arranging for their patients to be interviewed for contacts by a trained interviewer from the health department. The percentage of patients interviewed under this program increased to 97% in the three-year period after its inauguration.

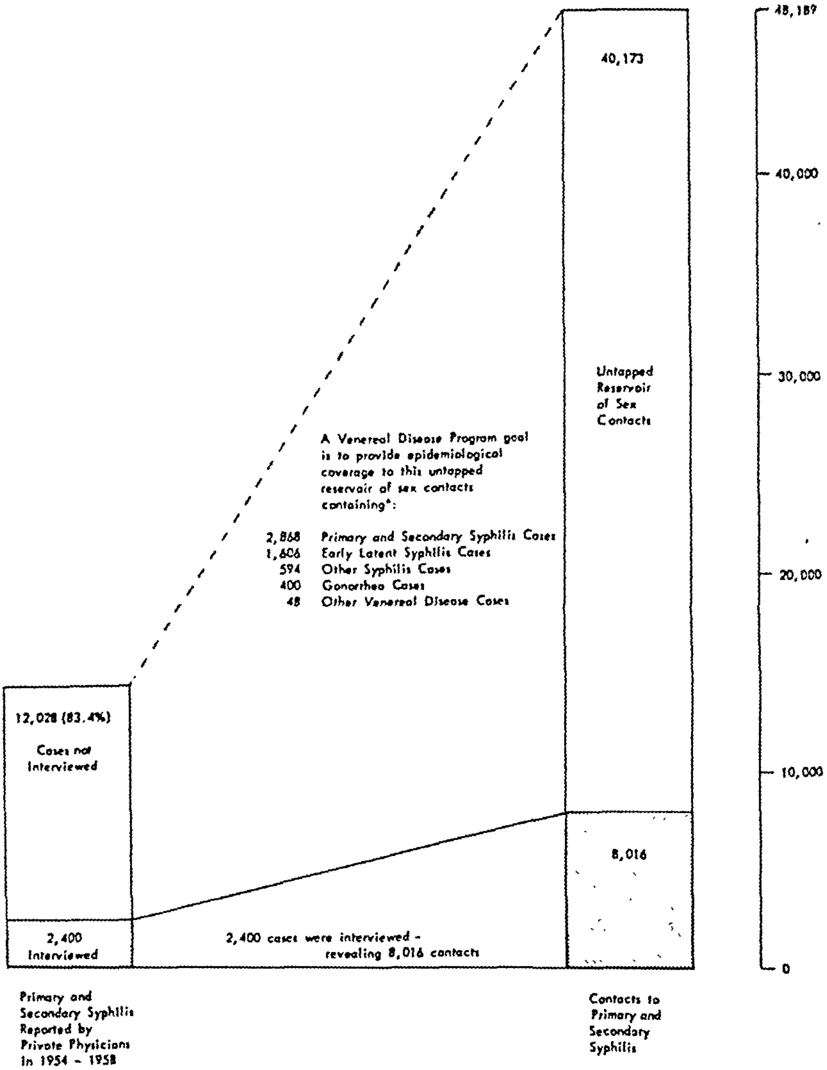

Fig. 3.—Cases of syphilis seen by private physicians. Venereal disease program goal is to provide epidemiologic coverage of untapped reservoir of sexual contacts (*figures in chart based on national contact indexes).

If this program can work in one state, it can work in others. The plan is a simple one for the physician. He need only report all cases of syphilis and arrange for all patients with early cases to be interviewed for sexual contacts by a trained interviewer.

Trained Interviewers Available

The epidemiology of infectious syphilis requires time and effort that are at the disposal of few, if any, busy physicians. A properly conducted patient interview for contacts will consume an average of 45 minutes, and the available data prove that the most successful interviewing has been done by personnel who have had special training. Such persons have been carefully selected for their tact, integrity, intelligence, interviewing ability, personality, and their understanding of the confidential nature of their work. They are available through the local health department.

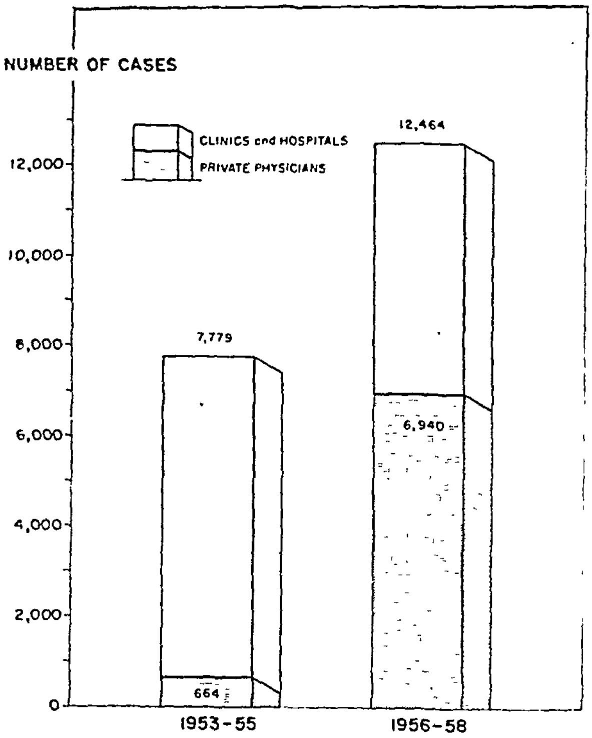

Fig. 4.—Comparison of cases of syphilis reported in southern state for fiscal years 1953-1955 and 1956-1958. Program of case reporting by private physicians was initiated in 1956.

In addition to the interviewing of patients, contacts named must be located in the field and brought to examination. Only health department personnel are able to do this adequately. Furthermore, many named contacts must be located in another city, county, or state. About 14% of all contacts named by syphilitic patients reside outside the state in which the case is diagnosed. In fact, with the increasing mobility of our population it is quite common to have contacts reported in far distant states and foreign countries. There is a national and international system of reporting such persons. Health department investigators follow their progress and bring most of them to examination and treatment if indicated. But such follow-up epidemiology cannot be carried out if the patient with the original infectious case is not interviewed.

Public health officers understand well the responsibility of the general practitioner to protect the confidence of the physician-patient relationship, as well as his reluctance to report the names of his patients with syphilis or to suggest that his private patient should be interviewed for contacts by a third person from the health department. Health department personnel concerned with venereal disease control have been trained to keep information concerning the identity of patients and contacts in strict confidence and to bring to the epidemiologic investigation the same high professional standards that are applied to diagnosis and treatment. Their approach to any person in a chain of infection considers marital problems and other social implications which might develop.

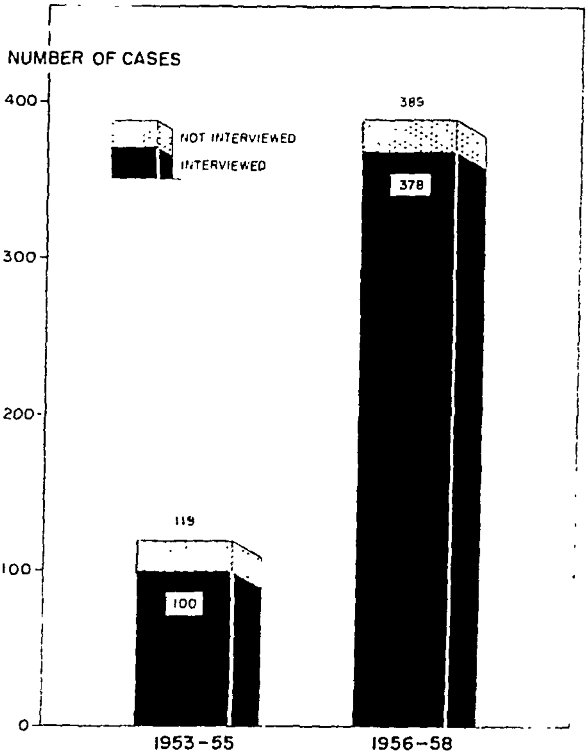

Fig. 5.—Comparison of cases of primary and secondary syphilis reported by private physicians in southern state and interviewed for sexual contacts for fiscal years 1953-1955 and 1956-1958.

Health officers, public health nurses, and other health department personnel trained in tracing contacts will cooperate in any possible way with the private physician, and the patient-physician relationship is often strengthened through their interviews. It should be stressed that the health department's approach to any private patient with syphilis is always with the knowledge and permission of the private physician. In fact, the health department representative approaches the patient in these cases as an agent of the physician.

Since the physician is busy and cannot be expected to devote the necessary time to interviewing patients for their contacts, it is most important that he call for the assistance of his local or state health department. If the trend line of infectious syphilis is to turn down again, physicians must first report all cases to the health department and arrange for health department personnel to interview their private patients for contacts. The greatest hope of further progress against syphilis in the foreseeable future lies in a private physician–health department partnership.

PHYSICAL MEDICINE AND REHABILITATION MANAGEMENT IN APHASIA

Jerome S. Tobis, M.D., New York

The relation of speech activity to other forms of motor activity was studied in 58 hemiplegic patients with aphasia. They were compared with another group of 51 hemiplegics without aphasia. Impairment of speech was found to be correlated with weakness of the hand; stimuli intended to elicit verbal responses often elicited motor responses of other kinds, and many aphasic patients when permitted to get out of bed, stand, and walk seemed to improve their ability to communicate. It is concluded that motor experience is important for language experience. The motor activities of dressing and walking either facilitate speech or otherwise facilitate the learning processes connected therewith. Occupational therapy reinforces speech therapy, and the two have been combined successfully in joint therapy sessions.

A speech disturbance may be an important diagnostic sign in a wide variety of medical conditions. Every physician takes note of the patient's speech in the evaluation of his medical status. Thus, a tremulous voice may connote fear or anxiety; scanning speech may signify a cerebellar lesion; a monotonous, flat speech of diminished volume may suggest parkinsonism. In all of these examples the finding may be of diagnostic significance. However, the management of the case need not be directed to the speech disorder.

On the other hand, major speech disorders such as aphasia or dysarthria may be disabling and invariably complicate the management problem. All too often the physician manages the problem of the paralyzed limbs, as in the hemiplegic, but considers the language disorder as a phenomenon discrete from the motor disability. The objective of this paper is to relate the language disorder of aphasia to the motor disability.

Language and Motor Skills

The relationship between language and motor skill has been clearly defined by Haldane,[1] who has stated, "The human brain has two super animal activities: manual skill and logical thought. Manual skill appears to be the earlier acquisition of the two and the capacity for language and thought has grown up around it. If we breed for qualities which involve the loss of manual ability, we should more likely evolve back to the apes than up to the angels."

Further support for this view has been forthcoming from Wundt and Bloomfield,[2] who proposed that motor acts in the form of gestures have been the source of speech. They consider that manual gestures became associated with oral gestures and these produced sounds. In this view, sounds became linked with the meanings of the manual gestures and subsequently the manual gestures were eliminated. It is in this light that emphasis is placed on motor experience as essential for language experience.

The effort to deal with aphasia as a purely psychological or linguistic phenomenon will lead to inadequate management. Tools of language come out of the experience of manual function. On the other hand, the converse is also true. Walking,

---

Professor and Chairman, Department of Physical Medicine and Rehabilitation, New York Medical College.

Read before the Section on Physical Medicine at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 11, 1959.

feeding oneself, dressing, and other manual skills are more effective when directed by language and conceptual behavior.

The motor or efferent aspect of speech is expressed by the coordinated activity of maxillofacial and thoracic structures, including tongue, lips, larynx, lungs, and diaphragm. However, motor output is dependent on the sensory input. The close interdependence of sensory and motor activity has been emphasized by Gooddy,[3] who states, ". . . in voluntary movement, sensation and motion form a single, indivisible, continuous process." The general senses such as touch, pain, and proprioception and the special senses such as hearing, taste, and vision interpret the external environment to the patient. The total sensory input represents the combined activity of the end-organs, peripheral nerves, tracts, and the integrative sensory cortex.

With regard to cerebral lesions, brain damage generally disturbs the sensory input at the integrative level. In order to produce an appropriate motor response there must be an appropriate sensory stimulus. It has been shown[4] experimentally that sensory loss in an extremity abolishes motor function in that limb. It does not abolish the ability of the muscle to contract, but it prevents coordinated activity such as walking or exercise of manual skills. This dysfunction is comparable to that of the patient with receptive or sensory aphasia who may retain the ability to contract the muscles for the production of speech sound but whose speech function is inadequate for communication.

On the basis of these principles of sensory input, the aphasic patient will function most effectively in an environment that is well structured. Not only the quantity but also the quality of stimulation that he receives must be predetermined. Thus, some aphasic patients should live in an environment in which noise is reduced. For training purposes it may be desirable to reduce qualitatively certain of the sensorial experiences. Thus, a quiet, darkened room may be advantageous in the relearning process. On the other hand, in some patients more than one sensory modality may be used in order to reinforce the impact on the patient's cortex. Thus, the therapeutic value of visual stimulation reinforcing auditory stimulation may have more than an arithmetic value. Its therapeutic effect may be geometric.

Quantity of stimulation must also be considered. There is both an upper and a lower level that is therapeutically desirable. Thus, a soundless room for the aphasic, as for the normal person, may be an oppressive experience. Recent experiments[5] on normal persons have shown that the reduction of sensory stimuli to a minimum may lead to serious psychic disturbances in the normal. Similar findings have been reported[6] in clinical situations. By the same token, such reduction of sensation may create further disorganization or even panic in the aphasic. Thus, the stimulus that is to be used must reach the minimum threshold which is appropriate to the level of organization of the central nervous system of the aphasic patient. This threshold will vary for each patient.

A third area in which speech as a motor function should be reviewed relates to visceral functions. The receptors and effectors which have been mentioned previously have dealt primarily with the voluntary and somatic aspects of the nervous system. Reflexes mediate activity of the respiratory, cardiovascular, and endocrine systems, which factors can modify the speech function. For example, modification in respiratory rate may reduce the volume of air for speech in the expiratory phase. Emotional lability will change the rate and tidal volume of respiration. Further, glandular activity of salivation may be inhibited by the autonomic nervous system, which may, in turn, lead to a thickened speech. Such changes reflect the intimate relationship of visceral innervation to the function of speech.

Thus far, similarities found in musculoskeletal functions such as walking and speech are rather apparent. However, there are significant differences. For example, if one walks endlessly in a circle it may be purposeless walking, but it is still recognizable walking. On the other hand, a flow of words in a sequence which has no meaning is not regarded as effective speech. Thus, a key function of speech as a means of communication is to influence the behavior of people, whereas other musculoskeletal functions may or may not serve this purpose.

Another significant difference relates to the nature of a functional increment in speech as compared to walking. If, for example, an aphasic patient is capable of relearning one or two nouns, is this as significant to the return of speech as one or two steps is to the return of walking? It is not, because as soon as the patient can take a few steps, one can predict that the patient will walk with some degree of facility, even though with a crutch. In the case of speech, one cannot as confidently predict the next increment by evaluating the accomplishment of the initial increment. This is so because, although the musculoskeletal act of enunciating words is a prerequisite of effective speech, it is not the equivalent of it. Thus, speech requires not only a motor act but also conceptualization, which represents the most complex and highest cortical activity of man. It is obvious, therefore, that in a patient in whom speech function has been seriously impaired, the rate of return may be much slower than for other motor function. This relates to a significant problem in the evaluation of speech therapy.

In a comparable situation of brain damage, our department has undertaken to evaluate 53 patients with cerebral palsy who had been on our inpatient service at Bird S. Coler Hospital.[7] We devised a system of values for some six categories of activities. These included motor functions such as walking, dressing, feeding, and going to the toilet. It also included the area of speech. The rating scales for each category were made as simple as possible and consisted of a hierarchy of items from total disability to complete independence. By the same token, we attempted to set a scale for speech, extending from total inability to communicate orally to normal communication for a particular age. In evaluating what our program had provided for these patients, it was most disturbing to find that by this rating scale the least gains had been made in the area of speech. On evaluation it became apparent that different criteria had to be established for measuring increments than those used for other musculoskeletal functions.

Rehabilitation of the Aphasic Patient

In the light of these considerations, I shall discuss some of our experiences in physical medicine and rehabilitation in the care of the aphasic patient. In the framework of the similarities between speech and other musculoskeletal functions, I have been impressed with the bodily movement which an expressive aphasic patient will employ. This will include gyrations of his head, arms, and legs in expressing the frustration that he presumably must feel in attempting to convey an idea to the listener. Because of this we have begun to study the possibility of a correlation that might exist between such aphasic speech disorders and motor function.

We have recently studied 58 hemiplegic patients with aphasia. In this group, 37 (64%) showed no motor power in the hand of the involved upper extremity. In a comparable group of 51 hemiplegics who showed no gross evidence of aphasia, only 14 (27%) showed no motor power in the hand. On the basis of this small series of cases, there would appear to be some correlation between the phenomenon of aphasia and complete loss of hand motor function.

Furthermore, we have also observed that many aphasic patients who are permitted to get out of bed and taught to stand and to walk often seem to improve their ability to speak or communicate.[3] There would appear to be some relationship between the improvement of musculoskeletal function and the improvement in speech function. We have also observed that, when an aphasic patient is asked a question, he tends to respond with a motor act. Thus, the patient may be asked if he can walk and he will tend to carry out the motor act. This might be considered to be a misinterpretation on the part of the patient. If the patient is advised not to walk and the question is again posed, the motor activity is often repeated. This may represent perseveration, but it signifies to me that a language experience, even when inappropriate, exhibits motor activity.

These observations which relate musculoskeletal function to speech function have led us empirically to the conclusion that motor experience is important for language experience. The motor act of walking or dressing may either facilitate speech or enhance the learning process that is involved in the complex signal or symbol system of verbal communication. Thus, therapeutic activity other than speech therapy may become a language experience. It is, therefore, we believe, important that the patient perform muscular activities which will reinforce his language function. In our department's treatment program, speech therapy is not necessarily restricted to the formal therapeutic session provided by a speech therapist. Rather, it is felt that all who provide care for the patient and who have developed a rapport with him also provide a form of speech therapy. We believe, therefore, that the physical and occupational therapists, in helping the patient improve his musculoskeletal function, are helping him to improve his ability for communication. We have instituted joint therapy sessions with speech and occupational therapy. In this program, motor activity is used to enhance speech therapy. Speech therapy should not be an activity that is conducted for one-half hour once, twice, or three times a week. It should, on the other hand, be an activity that is carried on daily, many hours each day, by the speech therapist, the physician, the physical therapist, the occupational therapist, the social worker, the nurse, and, perhaps most importantly, by the family itself.

Conclusions

I have attempted to view speech as a motor activity and to correlate the speech function with other musculoskeletal functions. In this framework, I believe that motor experience is important for language experience. Because speech therapy is so intimately linked with other therapy, it is important that the physician, with the assistance of the speech therapist, assume the responsibility for guiding the patient and his family relative to his speech disorder. Speech therapy should be provided not only during formal sessions but in all contact that the aphasic patient has with other human beings.

Finally, it is important that criteria should be developed in order to measure increments in the retraining of aphasic patients. Such measurements or tools will be more complicated than those for other musculoskeletal functions, because speech is dependent on many factors, namely, the biological apparatus as well as psychological, social, and environmental experiences. Thus, the development of effective measuring rods will probably require the cooperation of many disciplines, including neurology, speech therapy, psychology, sociology, and physical medicine and rehabilitation, among others.

In presenting these empirical concepts, one must understand the nature of empiricism. When empirical data become abundant to teachers and leaders of a field, it is necessary to abstract principles and concepts out of these data. I am hopeful that the field of physical medicine and rehabilitation may develop new approaches in the evaluation and management of the aphasic patient.

MASSIVE RESECTION FOR ILEITIS

TWELVE-YEAR FOLLOW-UP OF TWO PATIENTS

Mandel Weinstein, M.D., Morton Roberts, M.D.
and
Brian Reynolds, M.D., Jackson Heights, N. Y.

Surgical treatment of disease of the ileum sometimes involves removal of adjacent segments of jejunum and colon so extensive as to jeopardize the patient's postoperative nutritional balance. In the cases here reported two patients were studied 12 years after unusually extensive intestinal resections. One weighs 158 lb. (71.7 kg.) and is working full time although he lacks parts of the sigmoid and descending colon, the right half of the transverse colon, all of the ascending colon with cecum, all of the ileum, and all but about 60 cm. of the jejunum. The other retains about 45 cm. of jejunum and lacks the ileum, ascending colon with cecum, and half of the transverse colon; he weighs 142 lb. (64.4 kg.) and works as a truck driver. Both men compensate for poor water-absorption by a large daily intake of beverages and liquid foods, but they tolerate carbohydrates, proteins, and fats equally well. Their dietary habits and nutritional status show that they have made good adjustments to their handicap.

Many articles have appeared lately describing the successful removal of large segments of intestine for the complications of ileitis. Apparently nature's efforts to attain nutritional balance have been so effective that many of these patients have been able to enjoy comfortable and useful lives. These gratifying operative results have been made possible because of present-day advances in surgical technique, chemotherapy, studies of fluid balance, and a better understanding of intestinal physiology. The purpose of the present report is to render a 12-year follow-up study of two patients who required such extensive intestinal resections that as little as 18 in. of jejunum and small portions of the transverse colon and descending colon remained. At the time when both operations were performed (1947) and a preliminary report[1] made, a search of the literature revealed that no other patients with ileitis had had as much intestine resected.

However, the surgery for regional ileitis presents a more difficult problem than that of gangrene and extensive trauma to the intestines. In ileitis, the disease involving the intestine may be more extensive than appears evident at the time of operation. The typical patient with regional ileitis coming to surgery may be described as having a nonspecific, low-grade, inflammatory granulomatous disease of the small intestine, characterized clinically by the formation of an abdominal mass. Diarrhea, fever, and enteric fistulas are present. Contributing to the large size of the mass is the extension of the inflammation into the mesentery where edema and enlarged lymph glands are found. Not only do the inflammatory changes in the thickened and enlarged intestinal loops interfere with absorption in these involved areas but the disease has an irritating effect on the entire gastrointestinal tract, producing hypermotility of the intestines.

The end-results of massive resection are so variable that one cannot often predict which patients will obtain a good result or which will emerge from the operation showing extreme nutritional insufficiency. Not overlooking the fact that the length of intestine remaining is an important factor in determining the postoperative well-being of the patient, one is occasionally pleasantly surprised at the early and complete recoveries after some very radical operations. Fortunately, nature's compensatory mechanisms, plus the application of our increasing knowledge of nutritional requirements, have made these surgical successes possible.

Report of Cases

Case 1.—A 47-year-old man was admitted to the Boulevard Hospital on Feb. 2, 1947, with the history that in 1941 he had had a short-circuiting operation performed for regional ileitis; in 1943 periodic attacks of pain in the right lower quadrant developed, and he was admitted to a New York hospital where a second ileosigmoidostomy was performed. On Feb. 26, 24 days after admission, an ileostomy was performed for intestinal obstruction. Because of the poor condition of the patient, a mushroom catheter was inserted into a large distended loop of small intestine and a stab wound provided for its emergence in the right lower quadrant of the abdomen.

On March 20, 1947, another operation was performed. The operative procedure consisted of sectioning proximally through normal jejunum at a distance of 2 ft. from the duodenojejunal junction and removing the rest of the jejunum, the ileum, cecum, ascending colon, and hepatic flexure. A generous portion of thickened mesentery was removed with all excised intestine, and a lateral anastomosis was made between the remnant of jejunum and transverse colon. The area of the descending colon that was involved in the ileosigmoidostomies was also excised, a resection that included 8 in. of the descending colon and upper part of the sigmoid colon. Because of the extreme distention and edema of the descending colon, excision was performed according to the Rankin double-barreled colostomy technique. Postoperatively, the patient's condition immediately improved and he began consuming an enormous quantity of food. He manifested progress in every way, made an uneventful recovery, and rapidly increased in weight. He resumed his previous job as a carpenter and was able to work eight hours a day.

Twelve years after operation, in January, 1959, he weighed 158 lb. (71.7 kg.), more than before he became ill. His present occupation is that of a timekeeper, and even though he is 60 years old he is still able to perform a full day's work. In addition, he does odd jobs as a carpenter on week-ends. The bowel movements are loose and number five to six per day. They are so regulated that he has two evacuations before going to work and three to four after returning home in the evening. Thus, the condition is of no great inconvenience to him. Of course there is great thirst, especially in the evening, because of the water loss. He is strong and sleeps well throughout the night. He eats all foods except fruit juice, milk, cabbage, and spices. He even consumes three cans of beer every evening. He enjoys sweets, especially candy, and believes that this eradicates the occasional nausea he experiences in the afternoon. Meats of all kinds, even when fried, are eaten without any ill-effect. Fats do not upset his digestion, and bacon is a favorite food every day at breakfast time. The only medicament received is crude liver extract once every week hypodermically.

Laboratory data are as follows: blood sugar level 75 mg.%, blood urea level 14 mg.%, total cholesterol level 263 mg.%, cholesterol as esters 148 mg.%, total protein level 6.4 Gm.%, albumin-globulin ratio 4.0 to 2.3, carbon dioxide content 21.4 mEq. per liter, sodium level 137.6 mEq. per liter, potassium level 4.4 mEq. per liter, and chloride level 116 mEq. per liter. The blood count is normal, with a hemoglobin level of 11.9 Gm.% and 4,010,000 red blood cells. The urinalysis is essentially negative. Roentgenograms demonstrate an enormous dilatation of the remaining 2 ft. of jejunum, a compensating mechanism for the missing section.

Comment.—This patient is in unusually good health in spite of being left with only the duodenum and 2 ft. of jejunum (fig. 1). The cecum, ascending colon, right half of the transverse colon and the upper part of the sigmoid colon, and lower part of the descending colon are also missing. The portion of descending colon found diseased at operation was the result of an extension of the disease across an ileosigmoidostomy shunt. After 12 years, this case represents a complete ileitis cure since, apparently, all the diseased tissue has been eradicated. Functionally, the patient has an excellent result, considering the small amount of intestine that has been left to carry on nutrition. At first only carbohydrates were well tolerated, but later proteins and fats began to occupy a normal place in his diet. With the exception of a low blood sugar level finding, all laboratory tests show normal results.

CASE 2.–A 20-year-old man had been ill with symptoms of ileitis since he was 14 years of age. Within the past three years he had had three abdominal operations for this condition, but with no relief. On admission he weighed 117 lb. (53.1 kg.), a loss of 13 lb. (5.9 kg.) from his usual weight.

On Aug. 25, 1947, a massive intestinal resection was done, at which time there was removed a large abdominal mass consisting of inflammatory intestine and mesentery. Except for 1.5 ft. of proximal jejunum, all of the small intestine and ascending colon were diseased and therefore removed up to the middle of the transverse colon. A lateral anastomosis was made between the short jejunal remnant and the transverse colon. Postoperatively he did unusually well and was discharged from the hospital in 12 days. Two months after the operation he seemed to enjoy good health, was employed full time, and complained only of a few loose stools daily. His blood chemistry and blood count were essentially normal, and his roentgenograms already revealed a compensatory dilatation of the jejunal remnant.

About three years after operation, he began passing six to seven loose bloody stools a day. Sigmoidoscopic and roentgenographic examinations revealed ulcerative colitis in the remaining part of the large intestine. He improved under therapy consisting of antibiotics, iron, liver extract, and cortisone.

In October, 1957, he was readmitted to the hospital with rectal abscesses and severe debility. At operation the rectum was dilated for severe stenosis from scarring. Because of a low hemoglobin level, 4 pt. (1,893 cc.) of blood was given. He improved rapidly within a period of two months.

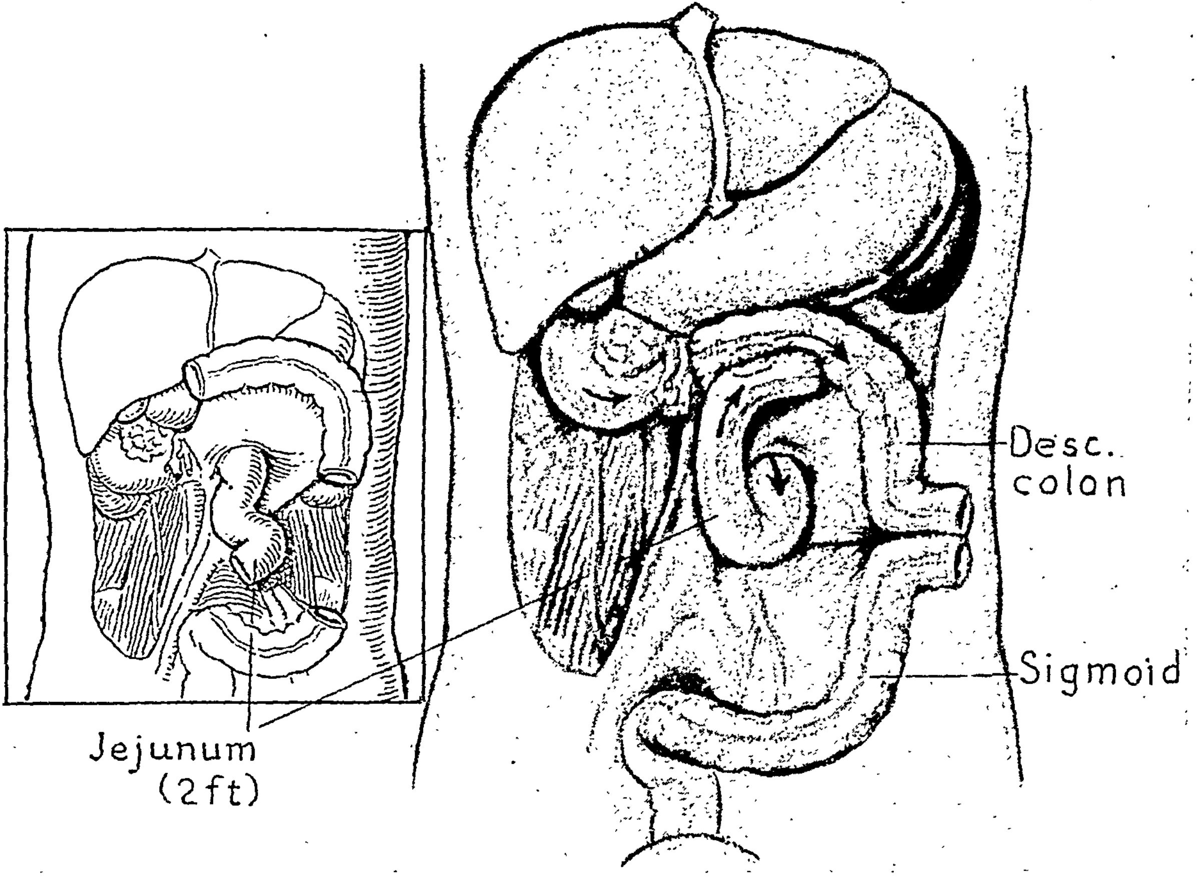

Fig. 1 (case 1).–Two feet of jejunum remain after excision of jejunum, ileum, cecum, ascending colon, right half of transverse colon, and 8 in. of descending colon and proximal sigmoid colon. Operation was transverse jejunocolostomy and Rankin double-barreled colostomy.

At the time of writing, 12 years after his massive intestinal resection, he feels that he is enjoying good health and works 8 to 10 hours a day, part of which time he drives a truck. His weight is at its optimum, 142 lb. (64.4 kg.), whereas, before operation, it was only 111 lb. (50.3 kg.). The stools are loose and number five to six a day. This creates great thirst, and he drinks tremendous amounts of fluids during the day. The only troublesome symptom is the distress from gaseous distention, at which time he notices his abdomen expand. Relief is afforded by the passing of large quantities of gas. His appetite is excellent, and he eats almost everything that the rest of the family enjoys except fresh fruit and raw milk. He particularly likes sweets, and sugar is a distinct "pick-up" for him. Meat of all kinds forms a large part of his diet; even fatty foods such as pork seem readily digestible. The only therapy is vitamin B_{12} and liver extract every one or two weeks. Gelusil tablets (containing 7.5 grains [0.5 Gm.] of magnesium trisilicate and 4 grains [0.25 Gm.] of a specially prepared nonreactive aluminum hydroxide gel) give him much relief from the gas.

Laboratory data are as follows: Blood sugar level 72 mg.%, blood urea level 13 mg.%, total cholesterol level 248 mg.%, cholesterol as esters 143 mg.%, total protein level 6.1 Gm.%, albumin-globulin ratio 3.5 to 2.6, carbon dioxide content 24.5 mEq. per liter, sodium level 132.4 mEq. per liter, potassium level 4.0 mEq. per liter, and chloride level 116.0 mEq. per liter. Recent roentgenographic studies reveal a widened duodenum and jejunal remnant. The colon, especially the transverse colon, shows the presence of colitis in an inactive state. A recent blood count showed a hemoglobin level of 7.1 Gm.% and 8,700 leukocytes per cubic millimeter. However, in spite of no symptoms from this low hemoglobin level, he was given a transfusion of 1,000 cc. of blood.

Comment.—This patient was stricken at the age of 14 years with ileitis which involved the small intestine and ascending colon. A massive resection removed all of the small intestine, leaving behind only 1.5 ft. of jejenum (fig. 2). The ascending colon, up to the middle of the transverse colon, was included in the resected specimen. Three years after the operation an attack of ulcerative colitis set in involving the remaining part of the colon down to the anus. The question of involvement of the colon in regional enteritis appears to be controversial, but regional enteritis and ulcerative colitis may coexist.[1A] However, at the time of writing the disease is quiescent except for the fact that it has been resulting in lowering of the hemoglobin level. Intestinal compensability is remarkably good in that the patient eats all foods, even fat, without distress.

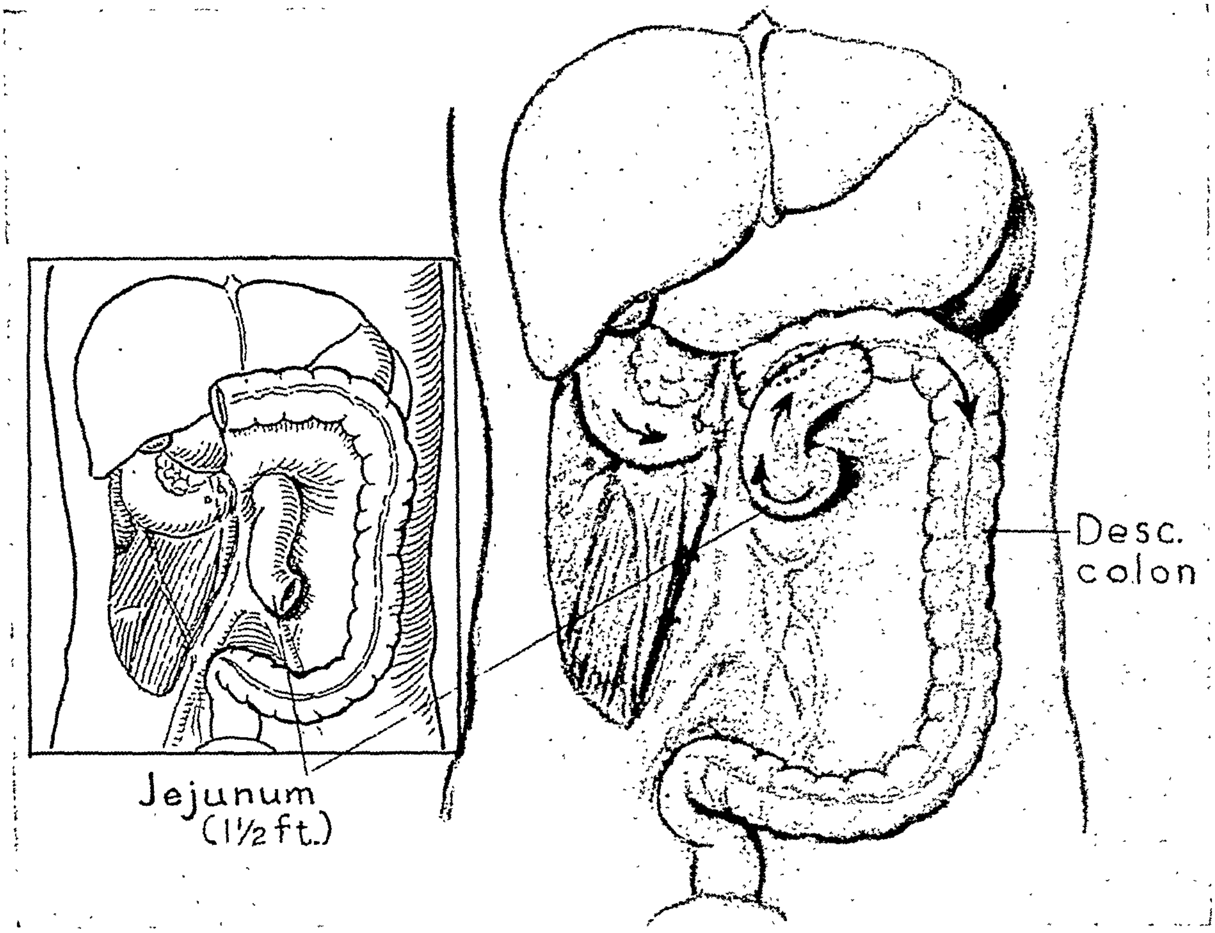

Fig. 2 (case 2).—Eighteen inches of jejunum remain after excision of jejunum, ileum, cecum, ascending colon, and right half of transverse colon. Operation was transverse jejunocolostomy and lateral anastomosis.

Pathological Physiology

In considering the causes of nutritional failure after the removal of large segments of intestine, obviously the loss of absorptive area must be given first place. But after operation the absorptive surface of the remaining intestine is greatly increased by a compensatory hypertrophy in the duodenum and the remaining jejunum. In some instances, this increase in the absorptive area of the small intestine has been estimated to reach 400%.[2] Histologically, the villi are more numerous in the duodenum and jejunum and the absorption rate is therefore greatest in these regions. The effect of this can be realized when one considers that the surface area of the intestine, averaging 0.5 sq. m., is increased by means of these villous projections to almost 10 m. Some state that the establishment of compensation is also aided by an increase in gastric secretion and that the gastric digestion rate is slowed to two hours or longer.

Undoubtedly the large intestine also plays an important role in compensation and as little as possible should be sacrificed at the time of resection. The ascending colon in particular should be retained, since its absorbing surface may help to counteract the most distressing symptom after operation, intractable diarrhea. Its action is also that of a reservoir, and by sufficient absorption of water and electrolytes the presence of the ascending colon can alter the consistency of the stools. Thus, it gradually acquires the ability to accommodate enormous stool masses and to extrude only once a day amounts up to one gallon at a time. Lillehei and Wangensteen[3] believe that water absorption takes place particularly in the terminal 30 to 40 cm. of ileum and is aided by the presence of the ileocecal valve. They feel that one can remove the colon itself without the patient's being troubled by too many stools, an argument they have advanced for encouraging complete colectomy in patients with cancer and polyps of the colon.

From a physiological standpoint, the small intestine is far more important for the absorption than the digestion of food.[4] The jejunum absorbs more fluid and sugars while the ileum absorbs the major portion of the digested proteins and fats. However, a resection of the upper half of the small intestine has no different end-results than resection of the lower half. These observations in patients who lost large segments of intestine at operation have changed many of our traditional ideas concerning intestinal physiology. One is impressed with the speed and thoroughness with which digestion takes place in the stomach, duodenum, and the proximal part of the jejunum, leaving very little digestion for the rest of the alimentary tract. No significant absorption of food occurs in the colon, although some contend that the colon contributes to the absorption of carbohydrates and proteins but not fat.[5]

Soon after massive resection, nutritional balance studies[6] carried out on human beings are in complete agreement in showing that the utilization of carbohydrates remains normal, the absorption of proteins is decreased moderately, and the absorption of fats is impaired severely. Although quantitative studies of the stool in cases of resection for ileitis show that carbohydrates are absorbed 100%, Althausen[4] has indicated that there may be some doubt regarding the accuracy of this procedure because of bacterial fermentation within the colon. Here fermentative bacteria may attack the unabsorbed carbohydrate, producing gas and organic acids; the extruded feces are then freed of carbohydrate. This may lead to a wrong conclusion concerning carbohydrate absorption.

Protein metabolism studies have uniformly shown that nitrogen balance can be maintained even though the length of remaining intestine is short. However, where nutritional failure occurs, especially soon after operation, protein metabolism is impaired. The result is a reduction of the plasma proteins, particularly the albumin fraction, and peripheral edema occurs. Since anorexia is often present, the hypoproteinemia may also be the result of a low caloric intake.

Fat is the food constituent most difficult to absorb according to all studies of metabolism. Although the bulky, rancid stools of steatorrhea are not commonly seen, these patients have diarrhea with a great loss of dietary fat in the stools. The result is deficient caloric content with its secondary effects on protein metabolism, calcium deficiency, and fat-soluble avitaminosis. The loss of calcium may result in hypocalcemia and occasionally in tetany. In some instances deficiencies in water-soluble vitamins B and C develop.

Even in patients with severe symptoms, all laboratory findings may be normal and render no clue as to the severe state of malabsorption present. In recent years, the literature has been replete with information concerning such contradictory findings. Trafford[7] has published a three and one-half year postoperative study of two patients with ileitis in whom all laboratory tests were persistently normal.

The adaptation of patients to the loss of large segments of intestine seems to improve greatly as the period of convalescence increases. As observed in both of our patients, whose conditions have been followed for a period of 12 years, fat and protein are now absorbed as readily as carbohydrates. Evidently intestinal compensation for nutrition is progressive, as manifested by both patients' being able to eat heartily of meats and fats. But the malabsorption of water remains almost unchanged and patients strive for comfort from the disturbing diarrhea by regulating their water intake according to their daily activity. Both follow the same habit acquired over the years, namely, emptying their colon of loose stools on arising and after returning from work.

Comment

A review of the literature for patients with ileitis does not reveal any follow-up study similar to this one that has been made for a period of at least 12 years. The most striking change in both of our patients has been a progressive adjustment toward being able to eat almost everything in a normal diet without any ill-effects. While immediately after operation they could digest and absorb only carbohydrates well, later their intestinal tracts became equally well adjusted to proteins and fats. The only postoperative symptom that has failed to improve has been the ability to absorb water. Even though the resulting diarrhea has not abated to any great extent, both patients have been able to regulate the time of evacuation of watery stools so that there has been little interference with their daily routine. All laboratory tests have been consistently negative with only one exception; the blood sugar findings in both patients have always remained at a low normal limit, 72 and 75 mg.%. Perhaps this is why they enjoy eating carbohydrate foods often and even feel that sugar in any form relieves their asthenia. The second patient, who also has colitis complications, occasionally shows a lowered hemoglobin level, a condition particularly evident when he suffered from perirectal abscesses.

In a general way, even though large amounts of important tissues are removed, the human body in many instances has the ability to adjust itself to altered conditions and to continue functioning efficiently. The first reason is that a great part of the tissue excised may be considered reserve tissue; not only do we possess a basic amount to carry on all the vital processes of our daily lives but an additional amount is present at all times. This can be readily seen in the field of chest surgery where, after pneumonectomy, the patient is suddenly deprived of more than half of his lung parenchyma and can still lead a fairly comfortable life. On the other hand, sufficient vital capacity is not available for those unusual physical demands such as running, jumping, and extensive pulmonary infections. The intestinal tract is similar in all these respects, and the successful recovery of the patient depends in great part on whether this basic minimum of functioning tissue is left behind.

Second, in considering intestinal equilibrium after resection, one must also bear in mind the nature of most tissues to undergo hypertrophy and hyperplasia. These compensatory changes are well known and result usually when tissues are subjected to additional demands. But such changes are possible only if the tissues are in a healthy state. Therefore, the need for removing all the pathological tissue at operation is obvious if the remaining parenchyma is to compensate unhampered.

Third, the associated structures of the intestinal tract, such as the liver and pancreas, are also involved in reestablishing intestinal absorption and digestion. The circulatory system and all the organs engaged in maintaining electrolyte balance are only a few of the other regulatory mechanisms called on for help. What other biophysical alterations may contribute to this remarkable compensatory state are as yet unknown.

Summary and Conclusions

Intestinal resection is an effective and relatively safe procedure today for the complications of ileitis, namely, obstruction, fistulas, and abscesses. Nutritional compensation is established early if no recurrence occurs or if no disease is left behind. Compensatory mechanisms are effected by dilatation of the duodenum and jejunal segment, hypertrophic changes in the intestinal villi, and a lessened need for a high caloric intake due to anorexia and weight loss.

Soon after the operation carbohydrates are well tolerated, protein only moderately, and fats not at all. Later on in the convalescent period all three are absorbed equally well. However, inadequate water absorption remains unchanged. A 12-year follow-up study of two patients, who at the time of their surgical operations had more intestinal tract resected for ileitis than any other patients up to that time, showed that, after extensive resection for ileitis, nature's generous supply of reserve tissue and great powers of adaptation and compensation make good health possible.

NEW TREATMENT FOR ULCERATIVE COLITIS

REPORT OF A FULMINATING CASE

Louis W. Granirer, M.D., Jamaica, N. Y.

After a short course of therapy with ACTH in small doses, combined treatment with gold salts, phenylbutazone, and vitamin B_{12} effected a dramatic recovery within one week. During the next two months the patient remained asymptomatic and was able to return to a virtually normal diet, including fried foods, green vegetables, and fresh fruits. Roentgenograms of the colon three months after treatment showed marked improvement, with no evidence of marginal ulcerations. The combined treatment may be administered continuously for long periods without ill-effects. The corticotropic hormone facilitated the control or bridged the initial severe phase.

The term acute fulminating or toxic ulcerative colitis refers to the disease in a desperately ill patient and is an episode of marked severity and intensity, associated with high temperatures and significantly elevated pulse rates over a period of several days.[1] It is fortunately uncommon, representing about 5% of all cases of ulcerative colitis, but it carries with it an extremely high mortality, irrespective of whether medical or surgical treatment is instituted. Crile and Thomas[2] found that 36% of patients with this stage of the disease died during the first hospital admission, regardless of the type of therapy used. Furthermore, of the patients followed up after their hospital discharge, an additional 32% died, giving a total mortality of 68%.

A favorable response previously recorded to therapy with gold salts, phenylbutazone (Butazolidin), and vitamin B_{12} in ulcerative colitis with arthritis was a valid reason for a therapeutic trial in a patient with acute fulminating ulcerative colitis.[3]

Report of a Case

A 32-year-old woman was first seen in January, 1959. The patient related that after the termination of a pregnancy two years ago she had been suffering from recurrent attacks of colitis, characterized by profuse unrelenting diarrhea, rectal discharges of mucus, pus, and blood, together with crampy abdominal pain, tenesmus, chills, and fever. Stool examinations, proctoscopy, and x-ray studies at another hospital confirmed the diagnosis of ulcerative colitis. Treatment included a bland diet and administration of sedatives, antispasmodics, opiates, salicylazosulfapyridine (Azulfidine), antibiotics, and ACTH in doses of 60 to 100 units daily. After 31 days the patient was discharged from the hospital with some decrease in the symptoms. She was switched from therapy with corticotropin to that with corticosteroids but did not respond to hydrocortisone, prednisone, prednisolone, methylprednisolone, triamcinolone, or dexamethasone (Decadron). The blood count remained low. She was advised to seek psychotherapy. Ten days before admission she had a recurrence of diarrhea, cramping abdominal pain, temperatures to 102 F (38.9 C), and had lost 20 lb. (9.1 kg.). She also developed a persistent stomatitis and remained bedridden at home.

Physical examination on admission revealed the signs and symptoms of an acute fulminating ulcerative colitis. The eyeballs were sunken, the skin was dry, the pulse rate was 150 per minute, blood pressure 90/60 mm. Hg, and the temperature 104 F (40.0 C). She was dyspneic and extremely pale and appeared to be in shock. She was disoriented as to time and place. There was generalized abdominal tenderness. Stools numbered 10 to 14 per day. Laboratory studies revealed a hemoglobin concentration of 5.2 Gm.%, erythrocyte count 2,100,000 per cubic millimeter, white blood cell count 18,000 per cubic millimeter, hematocrit 24%, erythrocyte sedimentation rate 60 mm. per hour (Westergen) plasma albumin level 2 Gm.%, globulin level 3.1 Gm.%, blood chloride level 240 mg.%, blood urea nitrogen level 35 mg.%, and blood sugar level 120 mg.%. The feces were positive for occult blood. Bacteriological examinations of the stool did not show specific organisms and microscopic studies revealed only excessive mucus and pus.

Blood typing was promptly done and saline solution and blood were infused at a rapid rate. In spite of supportive therapy with corticosteroids, opiates, sedatives, blood transfusions, and antibiotics the patient's condition remained critical (fig. 1). Examination of the colon by means of a barium enema showed extensive ulcerative colitis (fig. 2). On the sixth day a slow intravenous drip of 20 units of ACTH in 500 cc. of isotonic sodium chloride solution was started. She also received 5 mg. of gold sodium thiosulfate intravenously and 50 mcg. of vitamin B_{12} subcutaneously. The next morning she was mentally clear. On the seventh day 20 units of ACTH was administered intramuscularly every 12 hours. Administration of phenylbutazone, 100 mg., was begun orally and continued as a daily dose. On the eighth and ninth days the ACTH dose was 10 units twice a day. This was further reduced to 10 units once a day on the 12th, 14th, 20th, and 27th

---

Associate Physician, Queens Hospital Center.

days and then completely discontinued. The dosage of gold salts, in a 5-mg. dose with 50 mcg. of vitamin B_{12}, was maintained twice a week.

Within one week of treatment the number of bowel movements had decreased from nine to two daily. There was a dramatic improvement. The response was characterized by the disappearance of fever, toxemia, abdominal distention, and diarrhea. There was demonstrable healing of ulcerations in the mouth and in the colon, as noted in the proctoscopic examinations. The blood cell counts, sedimentation rate, and serum protein levels returned to normal, and the blood disappeared from the feces. The pulse rate dropped from 140 to 90 per minute. The total quantity of ACTH administered was relatively small (140 units), and the cessation of ACTH therapy caused no ill-effects.

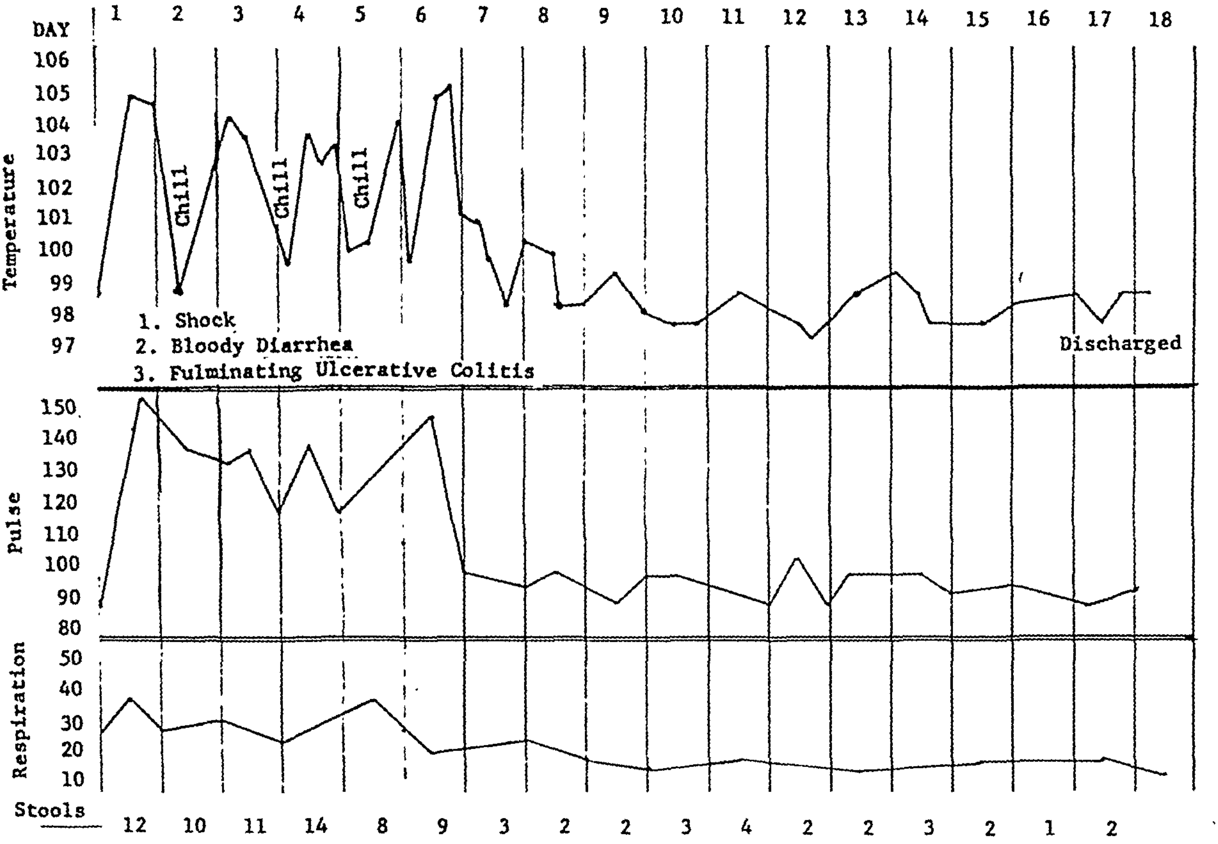

Fig. 1.—Chart of patient with toxemia, showing response to treatment.

During the next two months the patient remained asymptomatic, receiving a daily oral dose of 100 mg. of phenylbutazone and 5 mg. of gold sodium thiosulfate intravenously concomitant with vitamin B_{12}, 50 mcg. subcutaneously, twice a week. She was averaging three normal bowel movements a day.

At no time were there any dietary restrictions. She had a good appetite. Fat or fried foods, green vegetables, fresh fruits, nuts, fried potatoes, ice cream, tuna, ham, orange juice, cheese, steak, veal, or pizza pie did not induce diarrhea. Her menses became normal again.

The roentgenogram of the colon obtained three months after treatment showed a marked improvement with no evidence of marginal ulcerations (fig. 3). The frequency of gold injections was reduced to once a week, and the phenylbutazone dose was taken every other day. She had one to two normal bowel movements daily. At this time she stated that she felt well. She was completely rehabilitated and had gained 30 lb. (13.6 kg.).

Comment

Experience with this form of therapy is encouraging. In this case therapy with ACTH was used in a dosage sufficient to control the toxemia and the bleeding. The ACTH therapy was discontinued after a total dose of 140 units over 21 days, and this was considerably less than the amounts reported in the literature.

In an extensive review by Elliot and co-workers[4] of 33 patients with ulcerative colitis treated in hospital the dosage of ACTH was 100 to 120 units daily, gradually reduced to a daily maintenance dose of 20 to 40 units, and the total dosage amounted from 900 to 2,500 units. The late results of this therapy in six acutely ill patients with severe colonic damage were not striking, since an ileostomy had to be performed in three patients, ileostomy and colectomy in one, and chronic invalidism resulted from treatment in another.

In this case the corticotropic hormone facilitated the control or bridged the severe phase until the phenylbutazone and gold salts with vitamin B_{12} therapy corrected the disease process. From previous experience this usually requires from 4 to 12 weeks. There is little doubt that this therapy saved the colon and perhaps the life of this young woman.

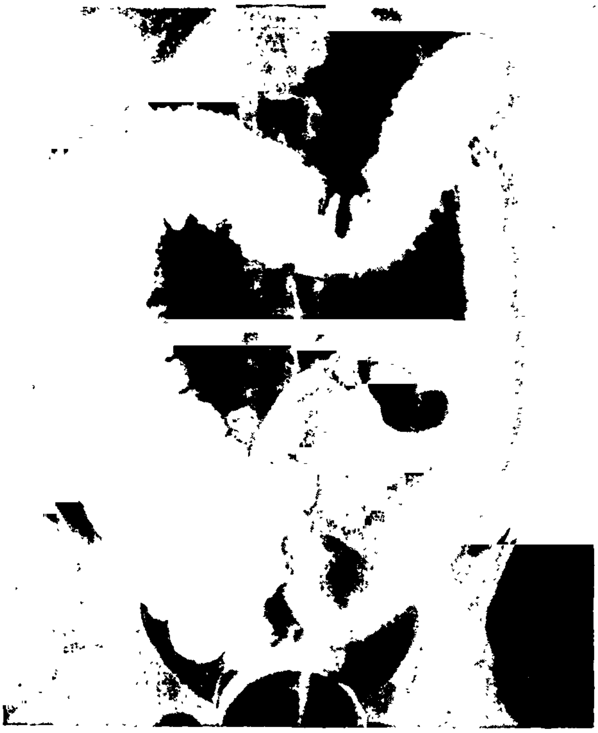

Fig. 2.—Roentgenogram taken on admission, showing extensive ulcerative colitis. Mucosal ulcerations are demonstrated throughout.

The association of ulcerative colitis with stomatitis, although not common, is of interest here. It usually denotes a severe ulcerative colitis.[5] This patient had a persistent stomatitis with ulcers on the tongue, alveolar margins, and mucosa. The ulcers were shallow and showed a yellow sloughy base. Some of the ulcers extended into the pharynx. The patient observed that the appearance of the stomatitis always preceded an episode of severe rectal bleeding. With therapy the ulcers healed and did not recur. She stated that this treatment seemed more helpful than any other form of therapy. The mechanism of the healing, as demonstrated in the stomatitis as well as in the colitis, remained nonspecific and may have been related to the sharp increase in protein values in the blood serum at this time.[6]

The treatment of ulcerative colitis is largely symptomatic and prolonged.[7] Patients with this disease are notoriously vulnerable, and recurrences are precipitated by physical fatigue, emotional tension, infection, operation, cathartics, antibiotics, menses, and pregnancy. In severe ulcerative colitis the response to medical management is frequently inconsistent or unsatisfactory and many patients become chronic invalids. Some authorities would place it among the collagen disorders.[8] Although it has been reported that arthritis is the most common complication of ulcerative colitis outside the intestinal tract, little has been written about it. The close relationship between the attacks of colitis and arthritis, and the improvement in the arthritis after colectomy, suggest an etiological relationship between articular and intestinal lesions.

From previous experience, it appears that therapy with phenylbutazone, gold salts, and vitamin B_{12} is more effective than the usual therapeutic measures. These may be administered continuously for long periods without ill-effects and under proper supervision appear to be useful adjuncts for the control of this disease. The response is gradual and usually requires 8 to 12 weeks. At no time need there be any dietary restrictions. Bowel habits become normal and the gain in weight varies from 10 to 30 lb. (4.5 to 13.6 kg.). ACTH therapy is not to be used except in toxic or fulminating ulcerative colitis and only for a short period.

There is evidence that this treatment is also beneficial in patients with regional ileitis (Crohn's disease).[3]

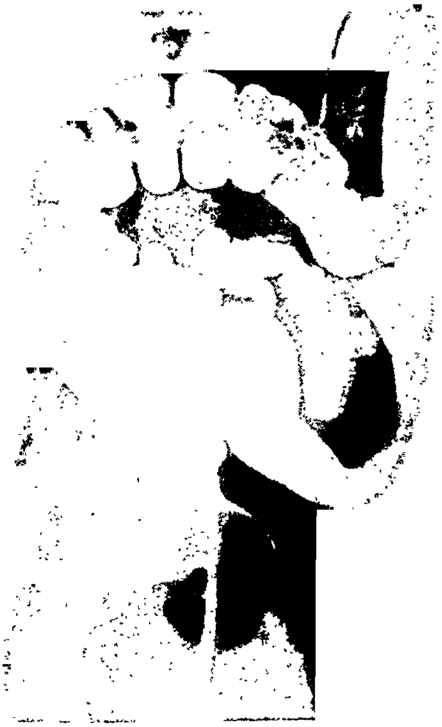

Fig. 3.—Roentgenogram taken three months after treatment with gold salts, phenylbutazone (Butazolidin), and vitamin B_{12}. The haustral markings have assumed normal configuration and there is no evidence of ulceration.

Summary and Conclusions

A patient with fulminating ulcerative colitis was treated with a short course of ACTH, gold salts, phenylbutazone (Butazolidin), and vitamin B_{12}.

There was a dramatic effect on the course of the disease. Roentgenographic as well as clinical evidence demonstrated the beneficial effects of this form of therapy. Similar experience has been recorded in several patients with ulcerative colitis and arthritis. There were no dietary restrictions. In the patient whose case is reported here the colitis was completely controlled, permitting her to return to a self-sufficient and useful life.

90-36 149th St. (35).

The phenylbutazone used in this study was supplied as Butazolidin by Geigy Pharmaceuticals, Division of Geigy Chemical Corporation, Ardsley, N. Y.

EMERGENCY CARE OF EXTRADURAL HEMATOMA

Thomas V. Craig, M.D.
and
William E. Hunt, M.D., Columbus, Ohio

The patient with head injuries leading to extradural hematoma is most likely to pass through three stages: unconsciousness, a lucid interval, and recurrence of unconsciousness, with rapid deterioration. The relapse into unconsciousness denotes fulminating extradural hematoma and demands immediate action; the patient in this stage can no more tolerate delay than can a patient with respiratory obstruction. He cannot be transported long distances, and his hope lies in the general surgeon who first attends him. Usually, as in this case of a man injured in a motorcycle accident, the bleeding is from a branch of the middle meningeal artery. The operation here described provides an opening in the temporal bone to relieve intracranial presssure, allow blood to escape, and permit electrocoagulation of the bleeding point.

The extradural hematoma is generally felt to be the province of the neurosurgeon. It is not thought to be manageable in community hospitals even though it is often rapidly fatal when there is no emergency decompression of the cranial vault. It is therefore unrealistic to attempt to transfer such a patient to a neurosurgical center or to delay operation while a neurosurgeon is being summoned.

The mortality due to extradural hematoma is 50% in our hospital and in most clinics in the United States. This mortality has remained unchanged in spite of the striking improvement in mortality and morbidity of other craniocerebral injuries over the past three decades.[1] We believe that delay in treatment of extradural hematoma is responsible for the continuing high mortality. It would seem then that the responsibility for early recognition and palliative surgery in the smaller hospital must be placed on the general surgeon who is available.[2]

In this paper, we intend to reiterate the symptomatology and the emergency methods of attaining intracranial decompression prior to transportation for definite treatment to a neurosurgical facility.

Anatomy and Physiology

Extradural hematomas form between the dura and the skull. The bleeding source usually is a branch of the middle meningeal artery. This artery arises in the neck from the internal maxillary artery and enters the cranium through the foramen spinosum, grooving the inner surface of the temporal bone (fig. 1). The main branch lies about one fingerbreadth anterior and superior to the external auditory meatus. The artery usually has

---

From the Department of Surgery, Neurosurgery Division, Ohio State University Medical Center.

been torn by a linear fracture which passes through the temporal bone and the meningeal artery grooves. This fracture may or may not be demonstrated by roentgenograms. Its presence in this area certainly should alert the physician to the possibility of a middle meningeal artery tear in an otherwise normal patient. Temporal muscle edema overlying the fracture is an almost constant clinical finding and one which should always be sought.

The fracture, being the result of trauma, is most frequently associated with a brief period of unconsciousness which is not due to hemorrhage but to cerebral concussion. There is then a lucid period which represents the period of arterial bleeding and pressure build-up in the extradural space. Duration of the lucid interval depends, on the one hand, on the rate of recovery from the initial concussion and, on the other hand, on rapidity of development of cerebral compression from the accumulating extradural hematoma. If seen during the lucid interval, the patient will complain of severe headache on the side of the lesion. He also may be drowsy and nauseated and may vomit. The temporal muscle will be tense and swollen, but there may be no objective neurological signs. These signs are not long in coming, however, for a few minutes may present the physician with a dramatic picture of an unconscious patient with a dilated pupil fixed to light on the involved side and with contralateral hemiplegia progressing to decerebrate rigidity. This recurrence of unconsciousness is the terminal stage. Without immediate decompression, irreversible changes occur in the brain and death ensues.

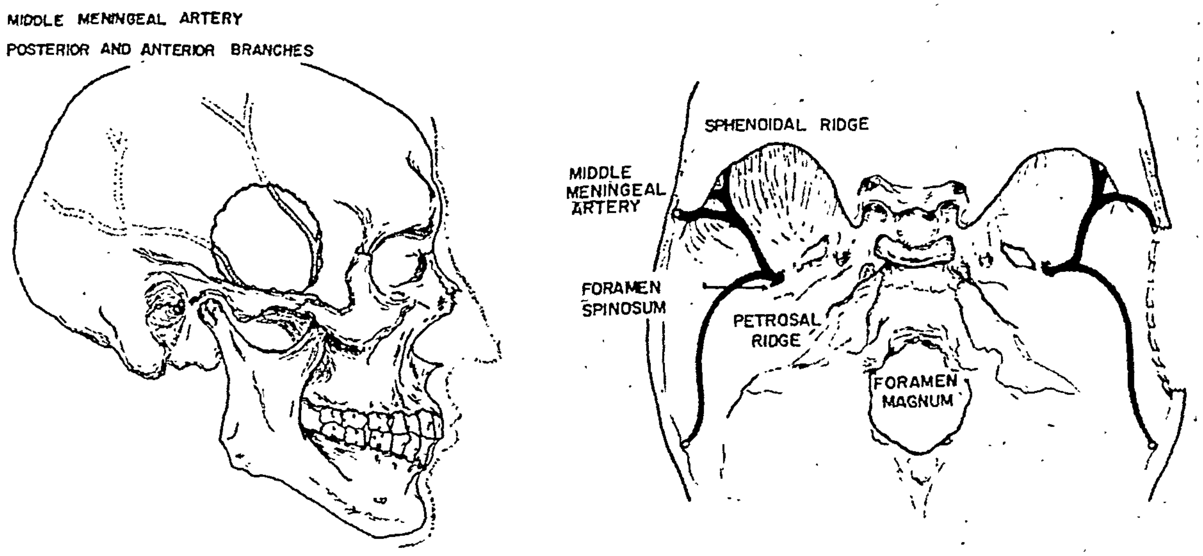

Fig. 1.—Diagram showing middle meningeal artery as usual source of bleeding in case of subdural hematoma.

How are the neurological signs produced? Pressure from the enlarging hematoma displaces the cerebral hemispheres and the midbrain. The uncus gyri on the medial surface of the temporal lobe is forced into the incisura of the tentorium cerebelli, compressing first the third cranial nerve and then the midbrain. This produces a paralysis of the opposite side of the body of the upper motor neuron type with hyperreflexia and an up-going toe sign. The third nerve paralysis is evidenced by an ipsilateral dilating pupil ultimately fixed to light and by possible paralysis of eye muscles. Further herniation of the uncus gyri against the midbrain compresses the vital centers, resulting in coma, decerebrate rigidity, stertorous breathing, and slowing of the pulse.[3] To recapitulate then, the classic history is divided into three stages: (1) unconsciousness due to concussion; (2) lucid period usually but not absolutely present; then symptoms of severe headache, drowsiness, nausea and vomiting, and the apprehension of impending disaster; and (3) recurrence of unconsciousness and rapid deterioration. This syndrome, when complete, will make its urgent nature apparent even to the casual observer.

Report of a Case

A 22-year-old man was admitted to our emergency room in coma. The history accompanying the patient was as follows: The patient had been rendered unconscious in a motorcycle accident but had begun to revive when first seen in an outlying hospital shortly thereafter. He tossed and groaned for about 40 minutes but did not respond to verbal stimuli. While he was being examined by the physician his right pupil became dilated and fixed to light and he became totally unresponsive. He was then transported to our hospital, arriving four hours after his injury, with a tentative diagnosis of extradural hematoma.

On examination, the patient was unresponsive to verbal stimuli and responded only slightly to pain with movement of the right upper and lower extremities. There was bleeding from the nose and both ears. The right temporalis muscle was swollen. The right pupil was 4 mm. in diameter and the left pupil 3 mm. in diameter, and both were fixed to light. There was hyperreflexia of the left upper and lower extremities but no response to plantar stimulation. Roentgenograms accompanying the patient showed linear fracture of the squamous portion of the right temporal bone. Immediately after admission, a tracheostomy was done. Suction of the trachea yielded large amounts of bright and dark blood. The patient was then taken to the operating room. A bur hole was made in the right temporal bone, and an extradural clot of dark and bright red blood was found. The bur hole was enlarged by rongeurs, and the massive clot, consisting of 500 cc. of blood, was evacuated. The anterior branch of the middle meningeal artery was still bleeding and was coagulated.

After operation the patient remained decerebrate. In spite of all supporative measures, his condition continued to deteriorate and he died 48 hours later. Postmortem studies showed a marked encephalomalacia of the cerebral hemisphere underlying the site of the extradural clot. There were extensive confluent midbrain hemorrhages.

Treatment

The emergency treatment of a patient with classic signs of fulminating extradural hematoma must be carried out with all possible haste, since the diagnosis is necessarily made in the terminal stage. No thought should be given to transporting this patient from a community hospital to a distant neurosurgical facility without first decompressing the extradural space. Establishment of an adequate airway is of prime importance and can be achieved by endotracheal intubation or tracheostomy. No attempt should be made to demonstrate a skull fracture by x-ray picture, as this requires too much time and often fails. Linear fractures of the temporal bone and basilar portion of the middle fossa are notably difficult to visualize, and patients with such fractures are often quite restless and uncooperative. If the patient is comatose, there is certainly no time for such refinements. Blood loss at surgery may be considerable, so type and crossmatch should be determined at the beginning of the procedure. Even local anesthesia may be unnecessary until decompression is accomplished, if the patient is deeply comatose. A headlight and suction are desirable but not essential.

Operative Procedure

After an appropriate area has been shaved, a 6-cm. vertical scalp incision is made and carried through to the bone. Its lower end is placed at the root of the zygoma one fingerbreadth anterior to the external auditory canal (fig. 2). Self-retaining retractors are used to hold the scalp and temporalis muscle edges apart. A bur hole may then be placed in the underlying temporal bone, or the bone may be opened with a gouge or chisel. Once the extradural space is opened, the hole can be enlarged with rongeurs in a radial fashion to a diameter of about 4 cm. If a clot is encountered, an attempt should be made to locate the bleeding point, which can be clamped, ligated, or electrocoagulated. If the bleeding point is deep in the middle fossa, the extradural space may be loosely packed, permitting some bleeding to the outside.[4] The scalp will bleed briskly when the self-retaining retractors are removed. They should be left in place unless Michel's clips are available for hemostasis. A loose dressing is applied over the wound, and the patient is readied for rapid transportation. It is imperative that a physician accompany the patient in an oxygen-equipped ambulance with blood or plasma on hand for use as indicated. This procedure, even in inexperienced hands, is a brief one and will offer the patient his only opportunity for recovery. Postoperative care of the patient, even assuming the surgery to have been definitive, should be directed by a neurosurgeon.

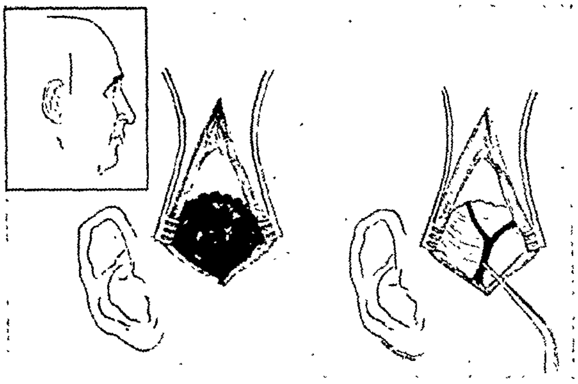

Fig. 2.—Sketch showing operative procedure in patient with subdural hematoma.

Comment

Standard surgical textbooks and manuals of general surgical and neurosurgical technique describe the treatment of extradural hematomas. They assume that it will be carried out by neurosurgically trained personnel. For the reasons presented above, this mode of treatment obviously is not applicable in outlying hospitals where neurosurgeons are not readily available. The patient with fulminating extradural hematoma can no more tolerate prolonged delay in treatment than can a patient with respiratory obstruction. While a few patients will present a similar picture from fulminating acute subdural hematoma, these patients have massive underlying brain concussion, and there is extremely high mortality with or without operation. Other patients with subdural or subcortical hematoma can be safely transported, since the deterioration of their conscious state will occur over hours or days.[5] We propose that a new attitude toward management of the extradural hematoma be invoked. The diagnosis and emergency treatment have been outlined.

Summary

The fulminating extradural hemorrhage classically has three stages—concussion, recovery, and then relapse of unconsciousness with ipsilateral dilated fixed pupil, contralateral hemiplegia, and terminally decerebrate rigidity. The fulminating extradural hematoma is often rapidly fatal. The patient should not be transported long distances prior to intracranial decompression. The responsibility for early treatment lies with the general surgeon who first attends the patient.

Treatment by intracranial decompression through an enlarged bur hole should be carried out with haste, since irreversible changes occur rapidly in the midbrain. After intracranial decompression, the patient should be placed in the care of a neurosurgeon and accompanied by the physician en route.

TREATMENT OF HYPSARHYTHMIA WITH ACTH

Fred W. Stamps, M.D., Erna L. Gibbs, Ira M. Rosenthal, M.D.
and
Frederic A. Gibbs, M.D., Chicago

Hypsarhythmia is a type of epilepsy which has, in the past, had an extremely poor prognosis. Eleven per cent of the patients died before the third year of life, and 87% of those who lived were feeble-minded. The present series of 60 children were treated with corticotropin for one year, with marked improvement in 36 and almost complete relief in 5 as judged by electroencephalographic criteria and subjective symptoms. The mode of action of the drug was not explained, and its effectiveness in the individual case could not be predicted from a knowledge of the etiology. By contrast with the poor results obtained in the past, these recent results with corticotropin are encouraging.

In 1957 at the International Congress of Neurological Sciences in Brussels, Sorel and Dusaucy-Bauloye[1] presented an exhibit showing that ACTH is highly effective for the treatment of hypsarhythmia and infantile spasms. In March, 1958, Sorel came to Chicago to attend a conference organized by the Brain Research Foundation to discuss this treatment and its implications.[2] A full-length report by Sorel and Dusaucy-Bauloye has been published recently.[3]

After seeing Sorel's exhibit in Brussels, we began, in October, 1957, to treat patients with hypsarhythmia with ACTH. The present article is a report on the first 60 consecutive cases of hypsarhythmia in which this treatment was used. Low[4] has reported a similar study with comparable results. Infantile spasms with hypsarhythmia is a distinct entity.[5] The characteristic electroencephalographic findings are random slow waves and spike discharges of very high voltage[5b]; these are present in both waking and sleeping states (fig. 1, 2, and 3). The spike discharges vary from moment to moment in both duration and location. At times they appear to come from a single focus, and a few seconds later they seem to originate from multiple foci. Occasionally the spike activity becomes generalized, but a highly organized pattern like that of either petit mal variant or true petit mal does not occur.

The pattern of hypsarhythmia usually develops between the 3rd and the 12th month of life. However, some of our patients were 1 day old, and one child developed spasms with hypsarhythmia at the age of 3 years. When the illness starts in the first few months of life severe mental and physical retardation usually results. Many of these children were unable to hold up their heads at 6 months of age, and many were unable to stand at the age

---

From the Department of Neurology and Neurological Surgery and the Department of Pediatrics, University of Illinois College of Medicine.

of 2 years. Several of the 6-year-old children could speak only indistinct single words. When hypsarhythmia develops after 12 months of age there may be a very rapid deterioration of the child's intellectual and motor status.

The spasms, which are the most usual clinical manifestations, are characterized by sudden jerking or flexion of the body; often the eyes roll up, and there is an outward flinging of the arms and quivering of the entire body. The attacks are short, but not so short as myoclonic seizures. Some of the infants have tonic-clonic convulsions that are classifiable as grand mal. The spasms are most likely to occur as the child awakens, and they tend to repeat, forming an interrupted series. Sometimes they are so numerous that several thousand spasms occur in a day.

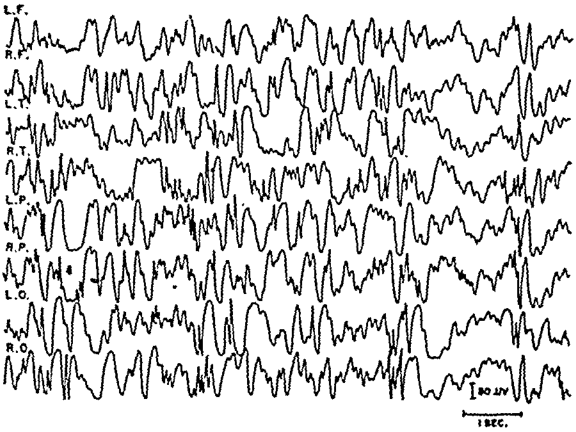

Fig. 1.—Electroencephalogram showing severe hypsarhythmia (waking and sleeping states indistinguishable), recorded on 7½-month-old infant with frequent brief spasms of turning the head, upward rolling of the eyes, and twitching of the arms, lasting for a few seconds. Onset at age of 3 months; retarded motor development; child does not sit up and is unresponsive; etiology unknown. Time calibration shows one second. Voltage calibration indicates the deflection for 50 µv.

The prognosis for a child with infantile spasms was extremely poor before the introduction of treatment with ACTH.[6] Eleven per cent of the patients died before the third year of life, and 87% of those that lived were feeble-minded. Although the seizures tend to subside by the fourth year of life even without treatment, retardation is permanent.

Materials and Method

An electroencephalogram was obtained on each child suspected of having hypsarhythmia, and the diagnosis was established before treatment with ACTH was begun. All recordings were made with the patient in both waking and sleeping states. The recordings were monopolar; interconnected ear lobes were used as a common reference, but this is unimportant because hypsarhythmia is a disorder that can be seen as easily in bipolar as in monopolar recordings.

As soon as the electroencephalographic diagnosis was established treatment with ACTH was begun. Infants were given (intramuscularly) 5 units of corticotropin gel (Purified Corticotropin-Gel Wilson) daily for five days. This was increased to 10 units after 5 days and 15 units after 10 days. On the 15th day the electroencephalogram was repeated. If there was clinical or electroencephalographic evidence of improvement the dosage of 15 units per day was maintained. If not, the dosage was increased gradually up to a maximum of 50 units per day. In one case the electroencephalogram normalized with the patient in both waking and sleeping states after 20 injections; the infantile spasms stopped completely and there was marked mental and physical improvement during the ensuing month. In a few cases, in order to obtain maximum benefit it was necessary to give as many as 120 daily injections.

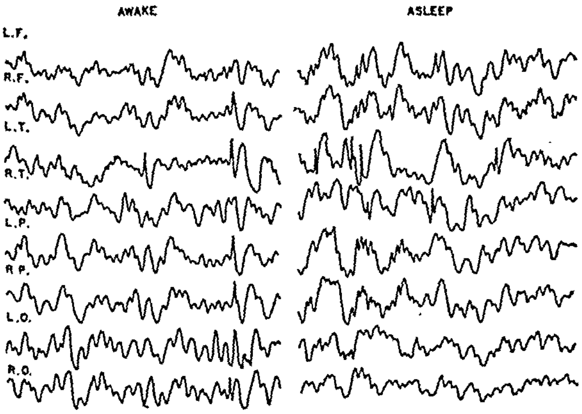

Fig. 2.—Electroencephalogram of same child as in figure 1 after 18 daily injections of 16 units of ACTH gel. Brief seizures are reduced in number and electroencephalogram is improved.

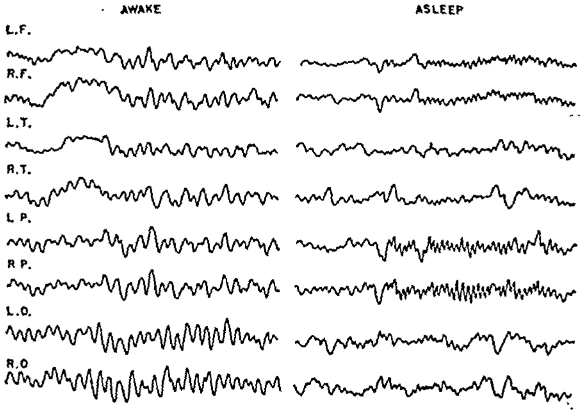

Fig. 3.—Electroencephalogram of same patient 30 days later after total of 54 daily injections of 16 units of ACTH gel. Normal electroencephalogram; no seizures have occurred for 20 days; child is able to sit up by himself and get up on his knees; he is responsive, alert, and apparently of normal intelligence.

Results

The table shows the number of patients whose electroencephalograms normalized and who became seizure-free. The number whose general clinical condition improved and the number unimproved are also shown. From these figures it will be seen that when the spike discharges disappear from the electroencephalogram the prognosis is good. In the five patients with complete normalization in both waking and sleeping states, all became seizure-free; three became completely normal clinically, two improved, none remained unimproved, and none showed relapse.

Among the 31 patients with marked electroencephalographic improvement, 42% were seizure-free, 40% were greatly improved, and only 18% were unimproved as far as seizures were concerned. The general improvement in motor performance and intellectual activity was similar to the improvement in the seizures; 10% became clinically normal and 50% were greatly improved. However, 30% showed relapse.

Further confirmation of the prognostic value of the electroencephalogram appears when one considers the 24 patients who were unimproved electroencephalographically; none were seizure-free and 96% were unimproved as far as seizures were concerned. None became clinically normal, and 96% were clinically unimproved.

Relationship Between Electroencephalographic and Clinical Response to ACTH Treatment

	No. of Cases	EEG After Treatment	Seizures						Motor Performance and Alertness							
			Eliminated		Decreased		Unchanged		Normal		Improved		Unimproved		Relapsed	
			No.	%	No.	%	No.	%	No.	%	No.	%	No.	%	No.	%
	5	Normal	5	100	0	0	0	0	3	60	2	40	0	0	0	0
	31	Improved	13	42	12	40	6	18	3	10	15	50	13	40	9	30
	24	Unimproved	0	0	1	4	23	96	0	0	1	4	23	96	1	4
Total	60		18	30	13	22	29	48	6	10	18	30	36	60	10	17

We have tried to analyze the etiology to determine the most usual cause of hypsarhythmia and to see if we could establish any relationship between etiology and response to ACTH. Each of the common infectious diseases of childhood was implicated in a few cases, but none seemed to be particularly likely to produce hypsarhythmia. In 28 of our 60 cases there was no history of illness just before the onset of spasms and the symptoms appeared suddenly without apparent cause. In 10 cases hypsarhythmia developed after encephalitis. Various diseases were involved: chickenpox, measles, virus pneumonia, and German measles. In one case triple vaccine injections were held responsible, but the association may have been coincidental. There were single cases in which the disorder was secondary to meningitis, otitis, and Mongolism respectively. Among the five cases in which ACTH normalized the electroencephalogram, made the patient seizure-free, and produced a general clinical improvement, no relationship could be found between the etiology and the therapeutic response. In this maximally responsive group each of the following etiologies was responsible for one case: German measles, roseola, upper respiratory infection, and cerebral palsy; in one case there was no assignable cause. When hypsarhythmia occurs in a patient with cerebral palsy it is usually difficult to decide whether the hypsarhythmia is the result of a developmental defect, anoxia at birth, or trauma. The situation is further complicated by the fact that babies with hypsarhythmia often become spastic after a number of years. The conclusion is not justified that spasticity indicates that the cerebral palsy is the cause of the hypsarhythmia.

In the conference organized by the Brain Research Foundation,[2] the question arose as to whether chlorpromazine might increase the effectiveness of ACTH therapy. Sorel had used chlorpromazine in the patients he treated with ACTH, and the incidence of great clinical improvement and normalization of the electroencephalogram in his series of cases was somewhat higher than in ours in which no chlorpromazine was used. We placed seven patients who did not respond to ACTH alone on therapy with chlorpromazine and ACTH. One patient became completely normal, three improved, and three patients remained unimproved. The question arose as to whether anticonvulsants might increase the therapeutic effect of ACTH. One patient who returned to normal was not receiving anticonvulsants. All others were on therapy with various combinations of diphenylhydantoin (Dilantin) sodium, phenobarbital, trimethadione (Tridione), primidone (Mysoline), and methsuximide (Celontin). A relationship between tranquilizers and anticonvulsants and the therapeutic effect of ACTH has not been established. The mode of action of ACTH in causing improvement in some cases of hypsarhythmia is not understood. It is also not clear why some patients fail to respond to this form of therapy. At the present time one cannot predict in which case of hypsarhythmia the patient will respond to ACTH.

About 15 of the total series of 60 patients were hospitalized, and their electrolyte balance and steroid levels were studied. These investigations will be reported in a subsequent paper.

Summary and Conclusions

Before the introduction by Sorel of ACTH for the treatment of hypsarhythmia, the prognosis for patients with this condition was extremely poor; 85% became mentally retarded and 10% died. Electroencephalographic and clinical studies on 60 consecutive patients with infantile spasms with hypsarhythmia, some of whom have been followed up for over a year, indicate that ACTH therapy results in a dramatic improvement in at least 30% of such cases. When a good response to ACTH is obtained, the electroencephalogram normalizes, a great clinical improvement occurs, the spasms cease, and further retardation is prevented.

912 S. Wood St. (12) (Dr. Gibbs).

The corticotropin gel used for this investigation was supplied as Purified Corticotropin-Gel Wilson by Wilson Laboratories, Chicago.

GASTRIC PERFORATION IN THE NEWBORN INFANT

Leon C. Hamrick, M.D., Fairfield, Ala.

Perforation of the stomach wall in the newborn infant was first described by Siebold in 1825, and 81 cases have since been reported. Mortality is 81 %. Peptic ulceration was initially considered the cause of perforation, but congenital defects of the stomach wall and other etiological factors have now been defined. The first attempt to close such a perforation was in 1929, but survival after operation was not recorded until 1950. There should be little difficulty in making an early diagnosis and instituting proper treatment, if the possibility is kept in mind. Prompt identification and adequate supportive management during the preoperative and postoperative periods should decrease mortality.

Until recent years little had been written about perforation of the stomach in the newborn infant. This is not surprising, in view of the paucity of known cases. Vargas and others[1] have credited Siebold with publishing the first report of this entity in 1825. During the next century fewer than 10 cases were reported. However, within the past two decades more cases have been recognized and reported, bringing the total to 81. The over-all mortality in the cases reported is 81.5%.

Etiology

The cause of perforation in the initial cases was ascribed to peptic ulceration. In 1943 Herbut[2] shed new light on the subject when he found the perforation in a newborn infant to have resulted from a localized congenital defect in the musculature of the stomach. This finding has been confirmed by other observers.[3] Overwhelming septicemia with ulceration and necrosis of the stomach,[1] gastric ulceration resulting from intracranial hemorrhage sustained at birth,[4] stress and anoxia with resultant gastromalacia,[5] ruptured diverticulum,[6] distal obstruction,[7] intubation from tracheal suction or gavage feeding,[1] and abdominal trauma during delivery[8] have been cited as etiological factors. Cases have been reported in which no cause for the perforation could be found.[9]

From the Department of Surgery, Lloyd Noland Hospital.

Diagnosis

If one is aware of this condition, there should be little difficulty in making an early diagnosis and instituting proper treatment. In reviewing the clinical studies of cases reported, there is a striking resemblance in their histories. Although prematurity and congenital anomalies have been listed as associated findings,[10] the infant is usually normal at birth. Oral feedings are at first tolerated; however, regurgitation may be present. Stools are normal but may contain blood if an acute ulcer is present. After doing well for from one to several days after birth the infant has a fairly sudden onset of lassitude, dyspnea, and abdominal distention. This is followed by paralytic ileus, dehydration, and shock. The temperature and blood count are not remarkable. Nasogastric suction fails to relieve the distention, and fluids used for irrigation may not return. This should suggest that perforation has occurred.[1]

The diagnosis may be confirmed by a plain upright roentgenogram of the abdomen, which will show the presence of free peritoneal air. The superiority of the upright over the horizontal position for roentgenography is emphasized by Pendergrass and Booth.[11] The horizontal film may not show the pneumoperitoneum, therefore an upright film should always be made.

Treatment

In addition to supportive therapy with intravenously administered fluids and blood, vitamins, nasogastric suction, and antibiotics, surgical closure of the perforation must be done if these infants are to survive. Because of poor development of the omentum and the large size of the perforation which is usually present, walling off of the area does not readily occur spontaneously,[1] making surgical intervention mandatory.

The first attempt to repair a perforation of the stomach in a newborn infant was recorded by Stern and associates [12] in 1929. The first survival after surgery was reported by Legar and co-workers [13] in 1950. During recent years other reports of successful closures have been published [14]; to date 15 survivals have been reported.

Various incisions have been used to approach the stomach or upper part of the abdomen in the infant. We prefer a right transverse incision, which may be extended across the abdomen if further exposure is needed. On exposure of the site of perforation the edges may be seen to be necrotic and ragged. These shreds of tissue should be excised for microscopic study and to insure healthy tissue for closure. Griffin and Griffin [3b] stated that at surgery one cannot differentiate clinically between a perforated ulcer and a congenital muscular defect, since in the newborn infant the perforation is through a normal or slightly thinned wall, and the typical perforated ulcer as it appears in adults is not present.

Many perforations occur near the cardia, and this area should be carefully searched. After closure of the obvious perforation the stomach should be filled with warm sterile saline solution to check the repair and to detect other perforations, as suggested by Vargas and co-workers.[1] Obstruction of the intestinal tract must also be excluded before closing the abdomen, since this has been an associated finding in a significant number of cases.[14]

I prefer a two-layer closure of the perforation. Drainage of the peritoneal cavity is optional, but it is unnecessary unless there is a localized abscess. The nasogastric tube may be removed within 48 hours postoperatively and the infant started on small amounts of graduated feedings.

Report of Cases

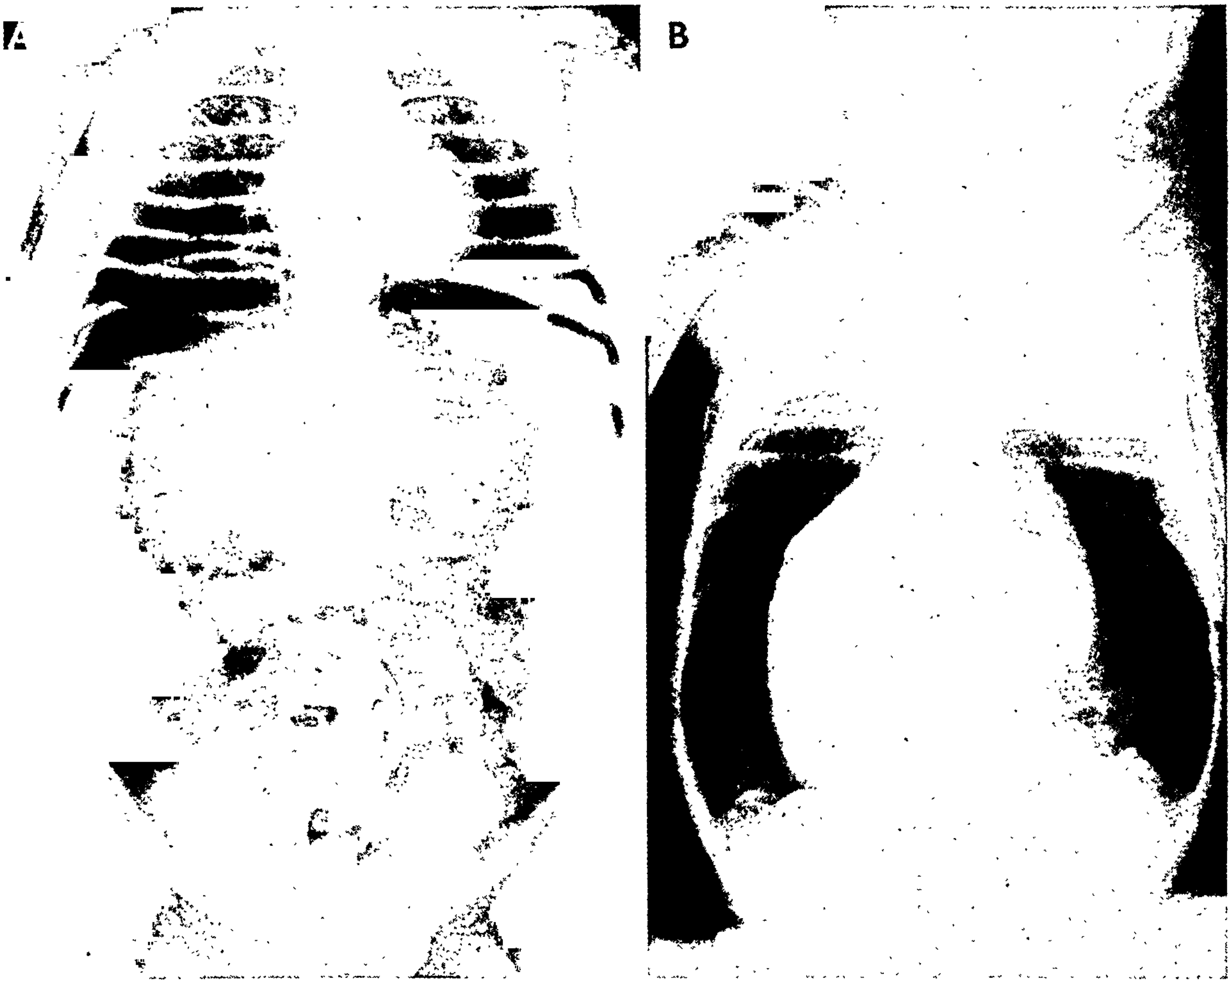
Case 1.—On June 12, 1939, a 3-lb. (1,361-Gm.) female baby was delivered spontaneously after six hours of labor. The condition of mother and baby was reported to have been good at birth. The infant was placed in an incubator and a formula was ordered. Neither tracheal suction nor gavage feeding was recorded as having been performed.

The infant died 41 hours after birth. Edema of the abdomen and signs of intra-abdominal fluid were described prior to death, but the time of these findings was not stated. At autopsy the abdomen contained a large amount of gas and fluid. Two circular perforations were found on the anterior superior aspect of the stomach, one of which measured 9 mm. and the other 3 mm. in diameter. The microscopic examination showed the region of the edges of the gastric perforations to be densely infiltrated with inflammatory cells, with normal muscle in the adjacent gastric wall. The pathologist registered no opinion as to the cause of these perforations.

Case 2.—On Aug. 16, 1950, a 7-lb. (3,175-Gm.) female baby was delivered precipitously. The cry was instant and vigorous. Examination at birth revealed abdominal distention and dulness to percussion. A nasogastric tube was inserted with little yield. A tentative diagnosis of a large intra-abdominal cyst was made. At 16 hours of life no meconium had passed and roentgenograms of the abdomen were made. These revealed free air beneath the diaphragm and an increased density in the lower part of the abdomen. Laparotomy was performed 23 hours after delivery. At surgery a large distended bladder, measuring approximately 15 by 8 by 7 cm., was found filling the peritoneal cavity. A linear perforation, measuring 4 cm. in length, was observed in the cardia of the stomach, and a volvulus from incomplete rotation of the intestine was present. The gastric perforation was closed, the volvulus reduced, and a suprapubic cystostomy carried out. In spite of adequate supportive therapy with parenteral feedings and antibiotics the infant died seven days after surgery.

Autopsy findings revealed peritonitis, a 2-mm. perforation on the anterior surface of the first portion of the duodenum, and incomplete rotation of the intestinal tract, with partial obstruction of the duodenum from a congenital band. Dilatation of the bladder and marked hydronephrosis were also present, without evidence of obstruction to the lower urinary tract.

The attending surgeon felt certain that the duodenal perforation resulted from the trauma of a plastic nasogastric tube, although the pathologist did not register this opinion in the autopsy protocol.



A, roentgenogram of abdomen of infant in case 3 taken in horizontal position; *B*, roentgenogram of abdomen taken in upright position.

Case 3.—On Dec. 6, 1957, a 4-lb. 14-oz. (2,211-Gm.) female baby was delivered by an elective low-forceps procedure after eight hours of labor. The cry was vigorous at birth and no resuscitative measures were taken. Since the infant was considered to be premature, she was placed on therapy with penicillin, streptomycin, and vitamin K. Formula feedings were begun at 24 hours. Several feedings were taken without incident. On the 3rd day of life three stools were passed which were described as containing a small amount of blood. Vomiting occurred twice on this day.

The infant developed marked abdominal distention, which did not respond to nasogastric suction, 76 hours after birth. Temperature and white blood cell count were normal. The abdomen became silent, and eight hours later roentgenograms of the abdomen taken in both flat and upright positions revealed a massive pneumoperitoneum (see figure).

Ten hours after the onset of distention laparotomy was carried out. On opening the abdomen a large amount of free air escaped, and a thick, milky exudate was seen extending from the stomach across the transverse colon to the right gutter. This was removed by suction, and a linear perforation, about 2 cm. in length, with ragged edges, was readily seen, extending transversely across the anterior wall of the distal end of the stomach. The edges were trimmed away and closure effected. The abdomen was closed without drainage.

Microscopic study of the edges of the perforation revealed only acute inflammation. Insufficient tissue was obtained to study the musculature of the stomach wall.

Postoperatively the infant did well, except for slow weight gain. She was dismissed from the hospital 28 days after birth. When last seen, at 4 months of age, she weighed 11 lb. (4,990 Gm.) and appeared to be a normal, healthy baby.

Comment

These case reports tend to emphasize the various aspects of the problems outlined in the general discussion. In case 1, multiple perforations and prematurity were present. Case 2 illustrates associated congenital anomalies, especially obstruction distal to the site of perforation, and the possibility of postoperative perforation from a nasogastric tube. Case 3 more readily parallels the clinical picture described in the majority of reports reviewed in the literature. While no definite cause for the perforation was found, it is easy to speculate that, had adequate tissue been removed at the site of perforation, a congenital defect in the musculature of the gastric wall might have been demonstrated.

Summary

Two of three newborn infants with gastric perforation died. The diagnosis was unrecognized in one patient until autopsy. One patient died after surgery, from duodenal perforation thought to be caused by prolonged intragastric intubation and unrelieved associated duodenal obstruction. One patient survived and is developing normally.

Awareness of this condition, early diagnosis, and prompt surgical treatment will reduce the high mortality associated with gastric perforation in newborn infants.

THE LEPROSY BACILLUS AND ITS HOST CELL.—*Mycobacterium leprae* can be introduced into human cells in culture where the bacilli persist for 1 and 2 months without demonstrable increase in the number of bacteria or appreciable host cell degeneration. While failure to elicit multiplication of the leprosy bacillus in cultured host cells means that a technique for providing large numbers of human leprosy bacteria for use in serologic and immunologic procedures is not yet provided by application of cell culture techniques, it is possible that the system as employed in the current work will provide a test method useful in screening drugs for antileprosy activity. The observation that the cytoplasm of a rare host cell in an infected culture is filled with a hundred or more acid-fast bacilli 2 and 3 weeks after exposure to a suspension of leprosy nodule is worthy of special attention.—J. A. Morris and K. Nakamura, Behavior of Human Leprosy Bacilli in Cultures of Human Cells, *The Journal of Infectious Diseases,* July-August, 1959.

CLINICAL NOTES

HYPERSENSITIVITY TO IMMUNE SERUM GLOBULIN

REPORT OF A CASE

John E. Baybutt, M.D., Easton, Md.

The following case report, I believe, represents the first reported case of spontaneous hypersensitivity to immune serum globulin (human).

A 15-week-old male infant was brought to my office on Oct. 10, 1958. He had been exposed to an uncle living in the same house who was ill with infectious hepatitis. Because of this, the infant was given 0.6 cc. of immune serum globulin (human) which had been obtained from the Maryland State Health Department. The injection was made into the upper outer quadrant of the left buttock; a 2-cc. syringe and a 20-gauge needle which had been water-sterilized were used. The plunger was pulled back to assure that the needle was not in a vein and no blood was received.

Within 60 seconds after injection the baby became limp, was flushed all over, suddenly turned cyanotic, and stopped breathing. Within 15 seconds the baby was given an injection of 1 cc. of epinephrine in the same area of the buttock. He cried out and began to breathe and his color improved, but he continued to be limp. Two minutes later 2-cc. of diphenhydramine (Benadryl) hydrochloride was administered intramuscularly in the opposite buttock. He was wheezing and frothing at the mouth and was alternately flushed and cyanotic in the extremities, lips, and face. Five minutes after the first injection, because he continued to remain in a state of collapse, another 1 cc. of epinephrine was injected in the same area of the buttock and 10 mg. of prednisolone (Sterane) with ¾ grain (50 mg.) of secobarbital (Seconal) was given rectally. The area of the buttock in which the gamma globulin was injected became alternately flushed and pale. In about one hour his condition had improved so he could be transferred to the hospital. Just before he was transferred he began retching and vomiting and again became limp. He was taken to the Easton Memorial Hospital and put in an oxygen tent. His color improved, but he was still limp. His temperature was 99 F (37.2 C), pulse rate 170 per minute, and respiration rate 36. The eyes, ears, nose, and throat were essentially normal; the neck was supple; the lungs were clear; the heart was normal and no murmurs were heard. There was a deep firm indurated area 2 in. (5.1 cm.) in diameter in the upper outer quadrant of the left buttock, which remained during the infant's stay in the hospital, but has since disappeared. His reflexes were very active.

Blood count revealed a hemoglobin level of 11.8 Gm. per 100 cc. and leukocyte count of 13,250 per cubic millimeter with 1% juvenile neutrophils, 15% stab forms, 31% segmented forms, 45% lymphocytes, and 8% monocytes. The urine did not show pathogenic findings.

Three hours after admission, because of repeated attacks of cyanosis, another 0.5 cc. of epinephrine was injected intramuscularly and ¾ grain (50 mg.) of secobarbital was administered per rectum. He was also started on prednisolone therapy, with 5 mg. every eight hours. His condition remained good during the night; in the morning the prednisolone therapy was reduced to 2.5 mg. every eight hours and the administration of oxygen was discontinued. He took fluids well, and on Oct. 12, 1958, he was discharged from the hospital on a regimen of prednisolone therapy, 2.5 mg. four times a day for two days, then 2.5 mg. daily for one week. Seven days after his reaction to immune serum globulin he developed a mild upper respiratory infection, but had no further reaction in the nature of a delayed serum sickness.

The mother was 31 years of age and well. Her pregnancy had been normal. At three months she had an injection of poliomyelitis vaccine and at four and one-half months of pregnancy a wisdom tooth was extracted under local anesthesia. Two injections of penicillin were administered at that time.

The infant was born in Easton Memorial Hospital on June 30, 1958. Delivery was normal. He was examined in the hospital, and at 1, 2, and 3 months of age he was examined in the office. His growth and development had been normal. At birth he weighed 8 lb. 5 oz. (3,770.5 Gm.) and at 3 months of age, 16 lb. 2 oz. (7,314.2 Gm.). He was on a regimen of evaporated milk formula with a carbohydrate supplement (Dextri-maltose) until 3 months of age, when he was started on whole cow's milk. He ate baby foods and took 0.6 cc. of vitamin supplement (Tri-vi-sol) daily. At 7 months of age he was well, weighed 21 lb. 7 oz. (9.8 kg.); was 28 in. (71.1 cm.) tall, and had had no other injections.

Family history revealed that the mother has had many allergies all her life. At present she is allergic to chocolate, cola, most nose drops, sulfonamides, and atropine. As an infant she had a severe reaction after each of her diphtheria injections. The father was 37 years old and well. Since the age of 6 months he has had eczema and continued to have it until three years ago. He received a medical discharge from the Army because of his allergy. In June, 1957, the father was given an injection of 17 cc. of gamma globulin prophylactically for mumps (epidemic parotitis). He developed a mild case of mumps.

The gamma globulin received by the patient in the case report was checked by E. R. Squibb & Sons. The lot in question, no. 277, had been prepared from human blood plasma and was normal in all respects. About 26,000 vials were shipped to 25 different locations in all parts of the United States, with no other reported reactions.[1] The gamma globulin remaining in the vial (1 cc.) was tested by intravenous injection into a rabbit and found to be sterile and nonpyrogenic.[2]

Dr. Charles A. Janeway, chairman, Commission on Plasma Fractionation and Related Processes, made the following comments on this case in a letter to Dr. Sam T. Gibson, director, Blood Program of the American National Red Cross, Washington, D. C.

> I think the outstanding features of this case are the tremendously severe allergic history in both parents of this child, which suggests that this child is the type of individual who reacts to antigens in an extraordinarily serious way. These are the people, certainly, who used to die following skin tests to detect sensitivity to horse serum, and are much more exquisitely sensitive than the individuals who have acquired a sensitivity as a result of previous exposure. The history of the use of therapeutic and prophylactic animal sera is replete with documented cases very like this one, and I would say that the physician was not only alert but very lucky to have saved this child's life. This is certainly the kind of baby I would be very hesitant about giving any type of injection to.
>
> It is interesting to speculate, first, as to whether this was an allergic reaction. I believe it was, but primarily on the basis of (1) the immediacy of the symptoms and (2) the heavy allergic history in the parents. It might also have been a vasomotor reaction due to intravenous injection of the type we saw in acutely ill children given intravenous gamma globulin, and the symptoms would be almost impossible to distinguish one from the other. I doubt if the dose was quite large enough to be responsible for this second type of reaction, particularly where the precaution of drawing back on the plunger was taken, so that only a small fraction of the dose could have been injected intravenously. Second, if this was an allergic reaction, then the mechanism is of some interest. The baby was only fifteen weeks old at the time of the injection. This might mean that this baby still possessed atopic reagins from its mother and that certain of the donors contributing to the gamma globulin solution might have eaten foods to which the mother had reagins. It is also possible that the mother is sensitive to such things as mercury, which might be present in the gamma globulin solution as a preservative. It seems fairly clear that the gamma globulin was acting as the shock antigen and that the hypersensitivity was in the child. This was not the passive transfer of reagins to a child with circulating antigen or the reaction would probably only have been local and milder, not general.

The only other report of a severe reaction to gamma globulin is that of Owings,[3] who on June 18, 1953, gave a 9-year-old female an intradermal skin test dose of 0.1 cc. of 1:100 gamma globulin; within one minute she became pale and went into anaphylactic shock. She was given diphenhydramine hydrochloride and epinephrine and recovered. She had had a previous gamma globulin injection in 1945. There are no other reported cases of sensitivity to gamma globulin, although more than 20,000,000 cc. have been distributed by the Red Cross and probably another 20,000,000 cc. by other agencies.

PSYCHIATRY IN THE PHYSICIAN'S OFFICE.—All physicians are constantly practicing psychiatry; . . . [it] originated with them. Doctors . . . must be many-sided, being neither totally organically nor psychiatrically oriented. They must recognize that all patients need emotional assistance and then administer psychiatric first aid. The physician needs to . . . ask himself, "Why is this patient this way?"; to be slow to give a purely organic answer (such as menopause), and to be even slower to use the much overadvertised psychiatric drugs. Every doctor should have at his fingertips: the psychiatrically-oriented history; the basic psychodynamics of human motivation; the clinical picture of most common emotional disturbances and psychotic reactions; skill in using the simple fundamentals of psychotherapy; [and] the fundamental technics of reeducation. . . . No purely psychiatric care can replace the understanding and knowledge of the family doctor. This is the background of good medicine.—W. B. Terhune, M.D., F.A.C.P., The Office Management of Psychiatric Problems: Psychiatry in the Physician's Office, *Medical Annals of the District of Columbia*, June, 1959.

COUNCIL ON DRUGS

Report to the Council

The Council has authorized publication of the following report. A review of the current status of knowledge of this important subject is offered as a guide to individualization rather than standardization in the application of specific immunological procedures to the management of tetanus-prone injuries. H. D. Kautz, M.D., *Secretary.*

SPECIFIC PROPHYLAXIS OF TETANUS

Geoffrey Edsall, M.D., Washington, D. C.

Although the incidence of tetanus in the United States has been decreasing during the past decade, several hundred cases still occur annually, in all walks of life and in all parts of the country.[1] The current situation has recently been well reviewed by Axnick and Alexander [1] who point out that, aside from the familiar hazard of tetanus after injuries and burns, there is still an unduly high incidence of the disease in relation to other circumstances, notably tetanus neonatorum.

Several publications on the management and prevention of tetanus have appeared within the past few years,[2] including an exhaustive review by Scheibel.[3] However, current literature and journal correspondence indicate that numerous areas of uncertainty persist regarding the prevention of tetanus. This status report attempts to assemble the existing basic knowledge on the subject, insofar as possible, and thereby to construct a rational set of procedures for the prophylaxis of tetanus. Necessarily, such a report on this complicated subject will be lengthy. For the convenience of the reader, the contents are summarized as follows.

- Active and Passive Immunization
- Use and Effectiveness of Tetanus Toxoid in Routine Immunization
  - Reagents and Procedures
  - Indications for Active Immunization Against Tetanus
  - Effectiveness of Tetanus Toxoid
  - Immunological Response to Tetanus Toxoid
  - Interval Between Basic Injections
  - Response in Young Infants
  - Competition of Antigens
  - Duration of Effect of Primary Immunization
  - Maintenance of Tetanus Immunity—Routine Booster Dose
  - Frequency of Administration of Booster Dose
  - Reactions to Tetanus Toxoid
  - Response to Booster Dose
  - Rate of Response to Booster Inoculation
- Management of Patients with Tetanus-prone Injuries
  - Handling of Immunized Patient
  - Interval Between Emergency Booster Doses
  - Effectiveness of Combined Active-Passive Immunization in Previously Immunized Persons
  - Tetanus Prophylaxis in Unimmunized Patients
  - Active-Passive Immunization in the Unimmunized Subject
- Summary
  - Active and Passive Immunization
  - Use and Effectiveness of Tetanus Toxoid in Routine Immunization
  - Management of Patients with Tetanus-prone Injuries

Active and Passive Immunization

Prophylaxis against tetanus may be achieved by either active or passive immunization or, under certain specified circumstances, by a combination of both. The differences between these two ways of achieving protection deserve to be reemphasized. Passive immunization is ordinarily induced by the subcutaneous or intramuscular injection of purified antitoxic horse serum. The protection achieved is rapid but transient. Detectable antitoxin appears in the circulation usually within a matter of minutes, reaches a peak after 2 to 3 days, and generally disappears in 10 days or longer, depending on the dose administered and the rate of elimination or inactivation of the immune horse globulin, which is related to the reactivity of the patient to horse serum.

Active immunization is a state achieved by injection of tetanus toxoid which acts as an antigen, stimulating the recipient to form his own antibodies. These, being autologous, are retained for a longer interval. Moreover, the production of new antibodies continues for a long period, and in addition such a process can be rapidly reactivated and greatly augmented by subsequent injections of toxoid. However, the initial development of significant antibody levels takes several weeks, so that immediate protection cannot be achieved by beginning active immunization.

Thus, passive immunization has the one advantage—sometimes a compelling one—of rapid effectiveness, but it has many disadvantages. The recipient of horse antitoxin not only makes no contribution to his own protection but actually reacts against it, by forming antibodies against the injected serum and thus accelerating its elimination. Severe anaphylactic reactions to the serum also

---

From the Division of Communicable Disease, Walter Reed Army Institute of Research.

occasionally occur. Moreover, an individual who has once been inoculated with horse serum (whether it was tetanus antitoxin or some other horse serum derivative) is likely to be sensitized against any horse serum preparation injected at a later date. This sensitization will generally lead to earlier and more marked serum sickness and will also lead to accelerated destruction of the antitoxin injected. In addition to these disadvantages, all of which limit the value of tetanus antitoxin, it is by no means entirely dependable as a prophylactic. Ever since World War I it has been well known that occasional cases of tetanus will occur in individuals given the standard prophylactic dose of tetanus antitoxin. Martini[4] cites two recent examples and summarizes many other similar reports. Still another important limitation to the usefulness of antitoxin is that it cannot protect against the considerable number of cases (reportedly as high as 50 to 60% of all cases of tetanus[5]) which occur in individuals whose injuries were so obscure or trivial that they were not treated by a physician. Finally, there is some evidence that the antibody resulting from active immunization is more effective, unit for unit, than that provided by passive immunization.[6]

Active immunization with tetanus toxoid, properly carried out, has essentially none of the disadvantages of passive prophylaxis. It is therefore the procedure of choice whenever it can be effectively employed, and it is widely practiced throughout the world.

Nevertheless, the prophylaxis of tetanus as currently practiced leads to a number of pertinent questions to which the practicing physician requires answers. The following questions are among those most commonly asked: 1. What is the actual degree of certainty that tetanus toxoid immunization, properly performed, will prevent tetanus? 2. How soon after completion of primary toxoid immunization (i. e., the first two or three injections, depending on the product and procedure employed) is a person immune to tetanus? 3. How long does this initial immunity last? 4. Should a reinforcing dose of toxoid be given and, if so, when? 5. How long does immunity last after basic immunization (i. e., primary immunization plus a reinforcing dose) is completed? 6. Are routine follow-up booster doses of toxoid indicated, and, if so, how often should they be given? 7. How long after a booster dose will a patient still be immune, and for how long will he remain capable of responding adequately and promptly to an emergency booster dose of toxoid? 8. How rapid is this response? Is there a difference in the rate of response, depending upon whether fluid or precipitated toxoid is administered, or upon the interval since the last booster dose? 9. Are there circumstances in which an injured patient with a valid history of toxoid immunization should nevertheless be given antitoxin as well as toxoid? 10. In the unimmunized injured individual, when should prophylactic antitoxin be given, and what is the optimal dosage under the various conditions seen in practice? 11. In such a patient, is it practical to undertake simultaneous active immunization with tetanus toxoid?

For some of these questions, fairly direct answers are at hand. For most of them, however, there are no data from which an answer can be obtained directly. Decision must therefore be based, insofar as possible, on experimental observations, modified or interpreted in accordance with the physician's judgment as it applies to the particular case which confronts him.

Use and Effectiveness of Tetanus Toxoid in Routine Immunization

Reagents and Procedures.—Active immunization against tetanus may be carried out with fluid toxoid (FT) or precipitated toxoid (PT; this symbol will be used to refer without distinction to alum precipitated, aluminum hydroxide adsorbed [Alhydrox], and aluminum phosphate adsorbed preparations, since there appears to be little basis for making any significant immunological distinction between them). Active immunization may also be effected with pediatric preparations such as diphtheria and tetanus toxoids combined with pertussis vaccine (Dip-Pert-Tet, Triple Antigen) (DPT) or combined diphtheria and tetanus toxoids (DT); preparations primarily applicable to adolescents and adults, such as combined tetanus toxoid and typhoid-paratyphoid vaccine (TABT) used extensively by the Canadian, French, and Italian armed forces, and "tetanus-diphtheria toxoid, adult type" (Adult Dip-Tet) (TD),[7] now used by the American armed forces and coming into general use for adolescents and adult civilians in the United States whenever immunization against both tetanus and diphtheria is warranted.[8] A new preparation now recognized for pediatric use is one combining diphtheria, tetanus, pertussis, and poliomyelitis antigens [8A] (Quadrigen, Tetravax).

Indications for Active Immunization Against Tetanus.—The indications for active immunization against tetanus are manifold. The reason for its extensive use and the ways in which community-wide immunization can be approached have been superbly set forth in a special report by the London, Ontario, Academy of Medicine.[2g] Since the inoculation of tetanus toxoid is virtually free of side-effects, and since tetanus may occur in any human being, there is no actual contraindication to making tetanus immunization universal. However, since this ideal cannot readily be achieved in the immediate future, the physician can focus his efforts on those groups in whom tetanus immunization is especially indicated. Thus, Christensen [2c] recommends tetanus immunization for (1) all child health programs, industrial immunization programs, or other routine immunization programs reaching large groups; (2) allergic individuals and those who have had previous injections of antitoxin or any horse serum preparation; these persons are most likely to be sensitive to antitoxin and therefore may be unable to receive it when they need it most; (3) patients who have been previously treated for tetanus, and who may therefore get only very transient benefit from it because of their accelerated response against horse serum as a foreign protein (contrary to a widespread belief, such patients need active immunization against tetanus; since this disease does not immunize against itself, numerous cases of recurrent tetanus have been reported); (4) various groups subject to an apparently greater than average risk of tetanus-prone injuries, i. e., farmers, hunters, operators of heavy machinery, particularly in the open where injuries incurred may be contaminated with dirt; and (5) military personnel. Some would add to this list pregnant women, particularly those women living in areas where tetanus neonatorum is common. This proposal has been criticized on the ground that immunization of expectant mothers may make it more difficult to immunize the young infant against tetanus, due to the interfering effect of maternally transferred antitoxin.[9] However, this difficulty can be surmounted, as noted later.

Effectiveness of Tetanus Toxoid.—Experience gained primarily in World War II has provided overwhelming evidence that tetanus toxoid immunization, adequately carried out, is one of the most highly effective immunization procedures ever devised.[10] The tetanus rate in the U. S. Army, which in World War I was approximately 13 per 100,000 injuries and fell to the lower level of 2.4 per 100,000 during the period between World Wars I and II, was held to the incredibly low level of 0.44 per 100,000 injuries (12 cases in over 2,500,000 injuries) in World War II. Of these 12 cases, only 6 had had any toxoid injections, and only 4 of these had had basic immunization plus an emergency booster dose. Five deaths from tetanus occurred, of which two had received an emergency booster dose. This is truly a remarkable record, particularly when compared to the experience of the Japanese army, of German prisoners of war who, except for the Luftwaffe and paratroops, were not immunized, and of civilians in tetanus-prone areas where fighting was intense and civilian injuries were widespread. The tragic story of tetanus among Philippine civilians during the liberation of Manila [10c] provided a striking contrast to the absence of tetanus among the Americans who fought and suffered injuries under the same conditions.

Just how effective is tetanus toxoid? No active immunization procedure is wholly perfect, and even tetanus toxoid is no exception. Several apparently genuine failures to achieve protection with tetanus toxoid immunization have been reported (see table). Some are inadequately documented, some followed incomplete initial immunization, several occurred years after primary or basic immunization, and a few had received basic immunization plus a routine booster injection. However, there have been seven reported cases (all in military personnel) whose records indicated that they had received basic immunization, as well as an emergency booster at the time of injury. These reports show that tetanus can occur in an individual whose record indicates that he has been adequately immunized against tetanus. Nevertheless, the exceptional rarity of such cases, particularly in the American and Canadian armed forces, indicates that the hazard of tetanus in a properly immunized individual is far less significant than many other day-to-day risks arising in association with illness, injuries, and surgery.

Tetanus in Immunized Persons

Author	Immunization Status	Cases, No.	Deaths, No.
Long[10a]	Primary only	2	0
	Routine booster 3 mo. previous	1	0
	Emergency booster	4	2
Hall[10b]	Uncertain	1	1
	Primary only	1	0

* Primary immunization in British army = 2 doses of fluid toxoid. Data based on British and Commonwealth troops only, as given in Boyd,[10e] table 4.

Except for the aforementioned record of failures, all information regarding the effectiveness of tetanus toxoid—including studies on the efficacy of various injection schedules, on fluid versus precipitated toxoid, on the duration of immunity, and on the timing of booster doses—can be based only on antitoxin titrations of immunized subjects. What do these titrations actually mean? Numerous attempts have been made to correlate circulating antitoxin levels with the degree of protection obtained. Obviously, the question can be answered only by analogy from results in experimental animals. Most of the available and informative studies on the subject were summarized and discussed by Looney and others.[11] Many investigators have selected 0.1 unit of antitoxin per milliliter of serum as the "threshold of protection," usually by analogy with levels observed up to a week after injection of 1,500 units of antitoxin. However, it has been found experimentally that levels below 0.01 unit may be sufficient to protect animals from death, although symptoms have occasionally occurred at higher antitoxin levels. Indeed, the early observations of Ramon and Descombey in horses, over 30 years ago, suggested that antitoxin levels of about 0.001 unit will give protection, and a remarkable human experiment supports this concept. Wolters and Dehmel [12] injected themselves with a dose of tetanus toxin calculated to be in the neighborhood of two to three human minimal lethal doses. At that time, each of them had a serum antitoxin level between 0.005 and 0.01 unit. Neither individual suffered significant symptoms after the inoculation, yet the amount of toxin given was sufficient to induce a booster response in each of them. Thus, despite the widespread acceptance of 0.1 unit as the "threshold of protection," there is very good reason to believe that a level of 0.01 unit or even lower is adequate.

Immunological Response to Tetanus Toxoid.—It is important to understand clearly the basic pattern of response which follows primary immunization and the subsequent administration of a reinforcing dose. The sequence of events has been vividly depicted by Evans,[13] whose findings may be summarized as follows. One month after the first injection *the response was barely detectable, if at all.* At this time a second dose was given. A fairly marked response occurred, the antitoxin level rising briefly to a peak titer averaging about 0.5 unit. However, at the end of about one year, the level had sunk to an average value somewhat below 0.1 unit. One-half of Evans' subjects were then given a third dose. Within 30 days their average antitoxin titer was close to 10 units. Most important, however, was the fact that one and one-half years later the subjects who had received a reinforcing dose still had levels averaging close to 0.4 unit, whereas those who had not received a reinforcing dose had fallen to an average of about 0.04 unit. Thus, the initial two doses, although they gave protection for upwards of a year, did not insure lasting protection. By contrast, the subjects who received a reinforcing dose at one year not only were well protected a year and a half later but possessed titers high enough to give a margin of protection for several years thereafter. Evans' findings are typical of the results obtained by many other investigators. Clearly, the importance of the "reinforcing dose" cannot possibly be overestimated. As stated by Christensen and Stilwell,[24] the 6-to-12-month "reinforcing dose" should be regarded as an "integral and fundamental part of the original immunization procedure," and not as a "booster" dose in the usual sense.

Thus, *there are three stages in adequate tetanus* immunization: the first injections, the reinforcing dose, and subsequent booster doses. The first injections will be referred to in this report as "primary immunization," whereas the term "basic immunization" will be used to describe the completed basic procedure which comprises not only primary immunization but an appropriately timed reinforcing dose as well. This concept of adequate basic immunization is, of course, already well recognized in the scheduling of poliomyelitis vaccination and most pediatric immunizations. Moreover, the importance of the reinforcing dose has also been clearly demonstrated in diphtheria immunization.[14]

The discussion which follows will generally be in terms of the use of precipitated toxoid for routine immunization, unless otherwise specified.

Interval Between Basic Injections.—It has long been known that the interval between injections has an important influence on the antibody response. During the past 30 years a number of investigators have shown, specifically for toxoids, that such antigens lose much of their efficacy if they are given in doses less than about three weeks apart. Sachs [15] has shown that six weeks may be even better. The minimum interval at which the reinforcing dose will be effective is not so clearly defined, but it is well established that lengthening the interval generally increases the effectiveness of the injection. Thus, the time at which this dose should be given is not rigidly fixed and may depend, in part, upon the circumstances of handling the patient. If the patient were to be unavailable for injection at the usual interval of 10 to 12 months (e. g., because of travel), *it is justified to give the reinforcing dose as* early as 6 months after initiating immunization. In other words, there are no absolute fixed intervals at which injections of tetanus toxoid (or of any other antigen) must be given, but there are minimum intervals below which the desired effect may not be obtained and maximum intervals beyond which it may not be safe to wait for completion of immunization.

Response in Young Infants.—Immunization of young infants against tetanus normally presents no problem,[16] but, *if done in combination,* as with DPT, difficulty may arise in inducing satisfactory immune levels against diphtheria or pertussis, due to the well-established interfering effect of antibodies transferred passively from the mother through the placenta. This inhibition of antibody formation in very young infants can be largely, but perhaps not entirely, compensated for by the reinforcing dose given 6 to 12 months later.[17] However, to avoid this problem, many schedules advise postponing immunization of infants with DPT until three to six months after birth.

On the other hand, the prevention of neonatal tetanus can be approached through immunization of pregnant mothers living in areas where neonatal tetanus is not uncommon. This has indeed been advocated,[18] but it has also been warned against,[9] *since it might interfere with effective neonatal* antitetanus immunization. Nevertheless, it would appear immunologically sound to employ antenatal tetanus toxoid immunization in areas where neonatal tetanus is a serious problem and then to establish adequate tetanus immunity in the infants, either by postponing immunization until age three to six months or by giving an extra dose of the immunizing agent as part of the primary immunization schedule.

Competition of Antigens.—From animal experiments it has long been known that, under certain circumstances, when two or more antigens compete, as it were, for the response of the antibody-forming tissues, the stimulus induced by one antigen may be suppressed. Barr and Llewellyn-Jones [19] have more recently proposed the vivid term "crowding out" for this phenomenon. Only recently Chen and his associates [20] have demonstrated that this phenomenon can be observed in man. They showed that, in children with preexisting diphtheria immunity, primary immunization with DPT led to lower tetanus and pertussis antibody responses than were found in children without such preexisting immunity. However, a later paper by Chen and co-workers[21] indicated that, after a reinforcing dose at one year, antitoxin levels in the two groups became almost identical. Essentially similar findings were obtained by Wiener, Patterson, and MacKenzie.[22] Thus, to date, there is no clear-cut evidence that the problem which might be created by "crowding out" cannot be surmounted by currently accepted immunization schedules.

Duration of Effect of Primary Immunization.—As noted previously, custom has dictated that the reinforcing dose is ordinarily given about one year after primary immunization, although it is permissible to give it as early as six months later. This implies the assumption that primary immunization will give the necessary degree of protection against unrecognized injuries for at least one year and that it will maintain responsiveness to a subsequent reinforcing or emergency booster dose of toxoid for this period of time. It is of interest that about 10% of American soldiers[23] and a higher proportion of Canadian soldiers[24] in World War II had titers below 0.01 unit one year after primary immunization. Nevertheless, the extremely low incidence of tetanus in these two groups suggests that the protection achieved by the procedures then used was exceptionally high. Since that time, the potency of toxoids has markedly increased, and in four more recent studies[25] only one small group, who were given two doses of fluid toxoid six weeks apart, has shown a comparable proportion of subjects below 0.01 unit at the end of one year.[15] Thus, it is safe to conclude that primary immunization with currently available toxoids, in adequate doses (i. e., at least two doses of precipitated toxoid or three doses of fluid toxoid), will serve its purpose as previously defined. However, it should be clearly noted that, if emergency tetanus prophylaxis is indicated during the waiting period between primary immunization and the reinforcing dose, a booster should be given. If such an emergency dose is given before six months have elapsed, it should be counted as part of the primary immunization. If given after six months, it should be regarded as the reinforcing dose.

From time to time special circumstances will suggest to the physician that, in a particular patient, augmentation of the primary immunization schedule may be desired, for example, if a patient were to be unavailable for the scheduled reinforcing dose. In any such situation—indeed, whenever the physician recognizes the need of an extra immunological stimulus for his patient (e. g., as with neonatal immunization)—an additional injection in the primary immunization schedule will accomplish the desired result.

Maintenance of Tetanus Immunity—Routine Booster Dose.—With tetanus immunization—as with most immunization procedures—after basic immunization has been established, each subsequent injection of the antigen leads to a rapid rise in the antibody level, followed by a drop which at first is rapid but later becomes very gradual; hence, measurable antibody levels usually persist much longer than after primary immunization. Successive injections of tetanus toxoid or certain other antigens induce successively higher peak responses, higher residual antitoxin levels, and longer periods during which antibodies are detectable. Thus, just as the reinforcing dose augments the protection begun with primary immunization, the injection of suitably timed booster doses will further augment the level of immunity and greatly prolong its effect. Actually, the function of periodic booster injections is twofold. In the first place, they reestablish a high level of immunity which normally lasts for several years, thus protecting the patient against tetanus infections arising from trivial or ignored injuries. Secondly, they maintain the subject in a state of responsiveness to toxoid, so that if an emergency booster is subsequently indicated, the patient will react to it promptly and vigorously. Thus, the periodic booster dose not only greatly enhances protection against tetanus but it obviates the occasional necessity of depending on antitoxin for prophylaxis because of uncertainty regarding the patient's active immunity status.

Frequency of Administration of Booster Dose.—There is as yet no basis for defining precisely the optimal interval between such booster inoculations. Some physicians have given them as frequently as every one or two years, but there is no clear immunological justification for such frequent injections. The American armed forces have adopted an interval of four years, which is apparently wholly satisfactory. Others have adopted or suggested five years or three years. The difference between three and five years appears to be immaterial; the main point is that some regular procedure should be adopted in order to insure that routine booster injections are not overlooked.

Several studies carried out during the past decade[26] indicate that the levels sustained after a booster, as well as the capacity to respond to a subsequent booster, are maintained for much longer intervals than was at first supposed. Bigler[25b] followed up 300 infants, for various intervals up to 10 years, who had been given two or more basic injections of diphtheria-tetanus toxoid. Every subject still had a measurable serum antitoxin level. Although high levels of antitoxin were less commonly found more than five years after the last dose of tetanus toxoid, many of these children retained high levels for as long as eight to nine years.

Similarly, in eight subjects observed by Regamey and Schlegel[26b] 10 years after basic inoculation with TABT, the lowest titer found was 0.075 unit. In 52 other subjects inoculated from one to nine years prior to the study, the lowest titer was 0.0075 unit. Looney, Edsall, Ipsen, and Chasen[11] studied a group of 144 veterans 1 to 10 years after their last inoculation of toxoid. Ten per cent of these subjects were found to have antitoxin levels below 0.025 unit per milliliter. However, the frequency of low titers showed no relation to the interval since the last injection of toxoid. Similarly, Turner, Stafford, and Goldman [25c] titrated tetanus antitoxin levels in 145 subjects, mostly veterans. Half of them had received their last dose of toxoid from 5 to 11 years previously, whereas the other half had been injected less than 5 years before the study. The median antitoxin level in the former group was tenfold lower than that found in the more recently injected subjects. However, only six subjects in the longer-interval group and three in the shorter-interval group had fallen to less than 0.01 unit when tested.

Equally well-sustained levels were observed by Peterson and colleagues [26c] in 200 veterans tested up to 13 years after their last tetanus toxoid injection and by Moss and co-workers [10d] in 100 Canadian ex-service men. The latter group included three individuals in whom the interval since their last inoculation was 11, 13, and 15 years. These three, incidentally, were the only ones in Moss' study whose titers had fallen below 0.01 unit. In the group studied by Peterson, 5 of 106 subjects observed seven or more years after their last injection had titers below 0.01 unit, whereas none of 41 subjects studied less than four years after their last toxoid injection were in this low range. Here again it appears that tetanus antitoxin levels will be sustained for a number of years after adequate basic immunization and a booster dose, with only a gradual fall in titer over the years.

This finding is not unique; similar results have been reported by Bojlen and Scheibel [14a] in children immunized against diphtheria with two primary doses of precipitated diphtheria toxoid and a reinforcing dose one year later. In these children the average antitoxin titers were essentially the same, whether the interval was three, six, or nine years after administration of the reinforcing dose.

These findings are consistent with the remarkable degree of clinical protection achieved in military personnel during World War II and in the Korean episode [10a] and with Ipsen's [8] finding that tetanus in civilian life has been markedly reduced since World War II among males in the veterans' age group. Thus, again it appears that the standard American and Canadian military practice is highly effective in preventing tetanus.

The data presented suggest the possibility that the interval between routine boosters might be lengthened to as much as 8 to 10 years. However, because there is a definite tendency for the antitoxin level to fall gradually [27] and also because data on titers at the longer intervals are relatively scanty, it would seem wise not to separate routine periodic boosters by more than four or five years.

Reactions to Tetanus Toxoid.—Annual booster injections of 0.1 cc. of toxoid given intradermally have been advocated [2f] as a method of insuring the maintenance of a "perennial state of immunity." Such a schedule has the advantage of regularity and convenience, although it has not been demonstrated that the "poor responder" will respond better to this schedule than to larger doses given less frequently. On the other hand, there may well be contraindications to overfrequent immunization, since a small but growing number of unpublished observations indicate that rather marked delayed-type local reactions—basically not unlike those seen in individuals sensitive to diphtheria toxoid—have occurred in people receiving tetanus toxoid after numerous previous inoculations of this substance. It is not unlikely that the repeated inoculation of any antigen may, in a small proportion of subjects, induce a delayed-type hypersensitive state of the type known as "tuberculin allergy" or "delayed bacterial allergy" and similar to the reaction to the tuberculin test or the Moloney test. Furthermore, it appears probable that such sensitization is somewhat more likely to result from the intracutaneous route than from other routes of injection.[28] Therefore, it appears wise to avoid overimmunization and to give only as many inoculations of tetanus toxoid as are clearly justified. It is worth mentioning that the presence of delayed-type hypersensitivity in a patient cannot, in practice, be ascertained prior to injection of an emergency booster dose of tetanus toxoid, as has been suggested.[29] Not only has no such test been standardized sufficiently to provide a basis for its interpretation but the wait of 24 to 48 hours required for reading the test would preclude its use in an emergency.[30] If doubt exists as to a patient's tolerance for toxoid and if an emergency booster dose is indicated, a small dose (e. g., 0.05 to 0.1 cc.) may be given subcutaneously and the rest of the dose given 12 hours later if no reaction has occurred. If a marked reaction should ensue, further toxoid injections at that time may be safely omitted, since it has been shown years ago that reducing the dose of tetanus toxoid does not proportionately reduce the magnitude of the response obtained.[31]

It should be noted that the delayed-type reactions are totally different from the immediate, urticarial-type reactions, occasionally reported as following the injection of tetanus toxoid. Some reactions of the immediate type have been shown to be due to the trace contamination of the toxoid with unrelated substances.[32]

In general, however, reactions to tetanus toxoid are so extremely rare as to be almost insignificant. Aside from the occasional delayed-type reaction noted and the rare reaction to extraneous substances, there are doubtless a few—a very few—individuals with a true allergic sensitivity to the toxoid protein itself. If such patients are observed, it is to be hoped that thorough immunological studies on them will be reported.

Response to Booster Dose.—A number of the studies cited have recorded the degree and in some cases the rate of the response to a booster dose, given from 1 to 15 years after the last previous injection of toxoid.[26] In general, when titrations are done seven days or more after a booster injection, only a few individuals will exhibit titers below 0.1 unit, and levels below 0.01 unit will be extremely rare. For example, all of about 140 subjects tested by Bigler one to two weeks after a booster dose showed ample antitoxin levels.

Regamey and Schlegel [20b] observed good antibody responses in all of their 60 subjects at intervals from 1 to 10 years after their last inoculation; the minimum titer observed by them (six days after the booster injection) was 0.15 unit. All but one of the subjects studied by Looney and co-workers [11] and all of the subjects studied by Turner and co-workers,[25c] Peterson and co-workers,[26c] and Moss and colleagues [10d] showed a good response to the booster dose. Thus, it appears well established that a routine booster dose of toxoid, given as long as 15 years after the last injection of toxoid, will induce a rise in antibody level, except in the rare individual who cannot respond to an antigenic stimulus.

Rate of Response to Booster Inoculation.—The rate of response has been under study for many years. Recent studies have employed larger groups and, in many cases, better antigens than the earlier studies, so that they probably provide a sounder basis for answering the question. In three subjects studied by Bigler,[25b] the injection of precipitated toxoid was followed by a rise in antitoxin level beginning in three, four, and five days respectively. Among Regamey's and Schlegel's 60 subjects, the lowest titer observed four days after the booster was 0.035 unit. Turner and colleagues found 2 out of 48 subjects with a level below 0.01 unit and 8 below 0.1 unit four days after a fluid toxoid booster; however, all had risen to >0.01 (and all but 2 to >0.1) by the seventh day. In Looney's group,[11] four subjects showed levels below 0.025 unit six days after a booster dose of precipitated toxoid. Two of these showed excellent subsequent responses; one (as noted previously) showed essentially no response at all, and one could not be followed up. Peterson and co-workers tested titers six to seven days after the booster. At this time all 216 of their subjects had levels above 0.01 unit, and all but two were above 0.1. Ninety-four of Moss' subjects, when tested one week after a booster injection, had a level of over 0.1 unit of antitoxin.

Miller and colleagues [33] noted that the speed of response appeared to be somewhat slower in subjects whose basic immunization had occurred more than six years earlier. The four subjects observed by Looney, who failed to respond within six days, had all received their last inoculation five or more years previously. These scanty data suggest that the rate of response may be slower when the interval since boosting has been longer, and thus give further justification to the recommendation that routine booster inoculations be scheduled at intervals no longer than five years.

Thus, it appears that perhaps 95% of subjects receiving a booster injection will respond within four days, and about 100% within seven days, even when 10 or more years have elapsed since the last inoculation. The few exceptions appear to be predominantly among subjects who have not received toxoid for over five years.

Miller and colleagues [33] compared the effect of fluid toxoid and precipitated toxoid, with regard to the rate of response after a booster injection. They found that increases in antitoxin titer (levels not given) appeared within four to five days in 30 out of 33 subjects given a booster with fluid toxoid, but in only 15 out of 34 subjects given precipitated toxoid. These findings have provided the basis for the widespread recommendation that fluid toxoid be used for emergency booster injections rather than precipitated toxoid. The findings of Schlegel [34] are similar; 13 out of 15 subjects injected with a booster dose of fluid toxoid (given seven to nine years after basic immunization with combined tetanus toxoid and typhoid-paratyphoid vaccine) showed a rise in level four days later, in contrast to only 1 out of 12 receiving precipitated toxoid. The studies of Volk and co-workers [35] on diphtheria immunization appear to provide additional evidence for the assumption that the response to a fluid toxoid booster may be somewhat faster than that to a precipitated toxoid. On the other hand, Ipsen,[8] using identical Lf doses of toxoid in paired experiments, found that with either 1 Lf or 5 Lf, the antitoxin levels reached at one week were five to seven times higher after administration of precipitated toxoid than after giving fluid toxoid. Moreover, neither Miller nor Schlegel stated the Lf titers of the toxoids they employed, so that it is impossible to tell whether their groups were genuinely comparable. Thus, the choice between fluid toxoid and precipitated toxoid for the emergency booster is still not unequivocally decided.

Management of Patients with Tetanus-prone Injuries

General application of the immunization procedures just discussed would prevent practically all cases of tetanus which might otherwise follow trivial or unrecognized wounds. However, each recognized injury must be considered individually, and the handling of such injuries varies according to the circumstances subsequently discussed.

It cannot be emphasized too often that the most important procedure in the handling of tetanus-prone injuries, regardless of immunization history, is adequate cleansing and débridement of the injury. Clearly, tetanus can occur only when susceptible tissue is infected with tetanus bacilli, and no history of immunization can eliminate the necessity of removing, insofar as possible, both the foreign material and the intruded epidermis which introduce tetanus infection and the necrotic tissue which nurtures it. The ubiquity in nature of the tetanus bacillus is not always fully recognized; it is independent of obvious "dirt."

As regards specific prophylaxis, various general recommendations have been outlined. Christensen [2e] advocates tetanus toxoid alone if the subject has an adequate history of toxoid immunization within five years. If over five years have elapsed, "particularly if the patient has a more serious injury such as a compound fracture, extensive burns, crushing injuries, gunshot or shrapnel wounds," he recommends giving tetanus toxoid and 1,500 units of antitoxin simultaneously at different sites. However, if the patient is sensitive to horse serum, he advises depending on toxoid alone. For the unimmunized subject who has sustained a tetanus-prone wound, Christensen advocates 1,500 to 3,000 antitoxin units, or more if indicated. He outlines in detail a procedure for testing patients for sensitivity to horse serum and for "desensitizing" positive patients with slowly increasing doses of antitoxin.

Parish, Laurent, and Moynihan [21] itemize the types of injury that require tetanus prophylaxis. They list (1) wounds over three to four hours old; (2) definitely infected wounds; (3) wounds through skin probably contaminated by soil; (4) all deep and punctured wounds; (5) wounds with devitalized tissue, e. g., crushing injuries; and (6) wounds that cannot be closed properly. They cite the fairly rigid definitions of "actively immune" and "non-immune" patients adopted by the British army several years ago, but which I find unduly conservative in the light of current knowledge regarding the response to primary or basic immunization.

The definition of the "non-immune" subject is not simple. Unfortunately, it must include all those subjects in whom there is a vague history or suspicion of a history of tetanus toxoid immunization but no definite confirmation. It will, perforce, include those subjects who say they have been "immunized" to tetanus but cannot specifically show that what they had was tetanus toxoid immunization, rather than tetanus antitoxin, diphtheria toxoid, "typhoid," or some other inoculation readily confused with tetanus toxoid by the layman. It will include individuals who have only had one dose of toxoid, and it should probably include individuals who had only primary immunization (but no "third dose" or boosters) more than five years previous to the injury in question. Finally, there is, of course, a large group of individuals who have clearly not had any tetanus toxoid inoculations. Thus, tetanus-prone injuries may be sorted into three categories, depending on whether they occur in a well-immunized individual, in an individual with waning or latent immunity, or in a patient with an inadequate, unreliable, or negative history of immunization against tetanus.

Clearly, the effective use of tetanus toxoid in the emergency prophylaxis of tetanus is dependent not only on adequate prior immunization but also on available and reliable evidence that this has been actually carried out. It is universally recognized and advocated [27] that veterans of military service may be regarded as having had tetanus immunization and may be handled accordingly. Over and above this, definite knowledge regarding a patient's immunity status is usually limited to a physician's own records. This is a deplorable situation and can only be remedied by a sustained, united effort on the part of the medical and public health professions.

It would be desirable for all immunized persons to carry with them a record of their tetanus toxoid injections; even though such records may get lost or may not be kept up to date, it is obviously better to have such records available frequently than not to have them at all. Parish [30] has recently stated the case for this practice lucidly and cogently and has advocated the use of metal disks for this purpose. To supplement such records, a central community file could be set up, maintained by the county medical society or by the health department.[28] When such personnel and central file records become generally available, much of the uncertainty which now clouds the handling of tetanus-prone injuries will be eliminated.

Handling of Immunized Patient.—From the data cited, it would appear that an individual with a history of properly performed primary tetanus immunization, administered within the previous five years, is virtually certain to show an ample response to an emergency or "wound" booster dose, beginning within five days after the booster injection. For such patients, a booster dose of toxoid should provide ample immunological protection against tetanus if it is given within 24 hours, regardless of the type of injury. If serious delay has occurred in giving toxoid and if the injuries are such that fulminating tetanus might be expected, then the physician may, in individual cases, weigh the advisability of giving 1,500 units of antitoxin at the same time, at a separate site. (Since 1950 the American unit and the International unit have been identical. Prior to this date an International unit contained one-half as much antitoxin as an American unit.)

When the interval since the last dose of toxoid has been more than 5 years and less than 10 years and when the patient has a clear-cut history of adequate basic immunization, an emergency booster dose of toxoid will be sufficient prophylaxis for ordinary injuries treated promptly. However, if delay has occurred in administering toxoid and if the risk of tetanus is self-evident (e. g., gunshot wounds, compound fractures, dirty wounds difficult to débride and expose), there is some theoretical justification for giving a simultaneous injection of 1,500 units of antitoxin. Even when more than 10 years have elapsed since the last dose of toxoid. prompt administration of a booster dose of tetanus toxoid will suffice to protect the patient in the vast majority of instances. Nevertheless, here the physician's judgment is paramount, and in such patients the procedure of giving a booster dose of toxoid simultaneously with 1,500 units of tetanus antitoxin is a justifiable, though conservative, method of providing additional prophylaxis in the presence of clearly tetanus-prone injuries. It must be weighed, however, against the likelihood of unfavorable reactions to the antitoxin.

Interval Between Emergency Booster Doses.—Frequently a patient is seen with a tetanus-prone injury, a few months after a known, recorded, previous booster dose of tetanus toxoid, and the thoughtful physician will naturally ask himself whether another booster dose is needed. Parish and colleagues [2j] have recommended that a booster dose which was given within the preceding 18 months renders another booster dose unnecessary. Others have set up a 12-month limit,[37] a limit of "a year, and possibly several years," [38] or a three-year limit.[26c] The available data do not provide a basis for an absolute rule on this question, but, in view of the extensive evidence [26] that protective antitoxin levels persist in a vast majority of subjects for much longer than a year, I would recommend a one-year interval of freedom from repeat booster injections except in patients in whom massive tetanus infection appears to be a definite hazard.

Effectiveness of Combined Active-Passive Immunization in Previously Immunized Persons.—Simultaneous administration of toxoid and antitoxin has been suggested previously as a method of handling certain situations in which genuine, serious doubt arises regarding the adequacy of a toxoid booster dose alone. This practice appears to be immunologically sound. Miller, Ryan, and Beard [30] demonstrated the efficacy of such a procedure in rabbits. They then gave 1,500 units of tetanus antitoxin and a booster dose of tetanus toxoid, simultaneously but in a separate site, to four patients previously immunized with toxoid.[30a] Three of their subjects showed vigorous antitoxin responses by the fourth or fifth day; the fourth subject showed essentially no response, and the authors believed that this subject was immunologically a poor responder. A larger group of 23 subjects was studied by Sachs [15] who gave 1 cc. of fluid tetanus toxoid and 500 units of antitoxin in opposite arms of the patients at the same time. By the 9th to 12th day, all subjects had titers from 1 to 100 units.

Thus, in certain selected previously immunized subjects, simultaneous active and passive immunization, achieved by injecting 1,500 units of antitoxin and (at a separate site) a routine booster dose of toxoid, provides a needed combination of immediate and long-term protection against tetanus. This procedure tides the patient over the period of uncertain protection during the first few days in those with waning immunity, potentially fulminating infection, or serious delay in administering toxoid. It should be borne in mind that the booster effect of the toxoid might well be blanketed if more than 1,500 units of antitoxin were given. Moreover, there is no immunological justification for larger doses of prophylactic antitoxin in such patients.

Tetanus Prophylaxis in Unimmunized Patients.—For unimmunized patients, the classic procedure, standardized toward the end of World War I, has been to administer 1,500 units of tetanus antitoxin as soon as the patient with a tetanus-prone injury has been evaluated for sensitivity to horse serum. Space does not permit a detailed discussion of the controversial views which are at hand regarding what constitutes an adequate basis for determining a patient's sensitivity to horse serum. The usual practice is to perform intradermal or conjunctival tests, or both, with epinephrine immediately at hand in the event of an untoward reaction.[2e]

On the other hand, Laurent and Parish [40] maintain that neither the intradermal nor the conjunctival test is reliable, both false-positive and false-negative reactions having been seen with both tests. They quite properly point out that a carefully elicited history of allergic conditions or previous serum injections is of paramount importance, and they would replace "sensitivity tests" with a small subcutaneous trial dose in persons with histories suggesting allergy. Their proposal to discontinue skin and eye tests will not be readily accepted unless more evidence is accumulated that such tests are misleading; however, the "trial dose" concept—if employed with great caution—would appear to deserve further careful study.

If it is not possible to débride the injury adequately, it has been customary to administer successive 1,500-unit doses of antitoxin at intervals of one to two weeks two or three times or until the wound has healed. It is undoubtedly true that this procedure contributed to the remarkably low incidence of about 1 case per 7,700 wounds or injuries in the United States army during World War I. Between World Wars I and II, the rate dropped further to 1 case per 40,000 wounds and injuries. This is really a remarkable record but is, nevertheless, short of the ideal of the practicing physician.

One suspects that the incidence of failure may be higher in civilian life. Certainly, there are numerous recorded instances in which the prompt injection of 1,500 units of antitoxin has failed to prevent tetanus. Hence, many physicians such as Martini [4] and Spaeth [2f] recommend giving 10,000 or more units of prophylactic antitoxin routinely in all cases in which its use is indicated. Others [2e] have suggested a range of 1,500 to 30,000 units depending on the circumstances, whereas many others [2h] stand by the classic dose of 1,500 units. Stotzer [2i] suggests that "rather than following a rigid standard (in employing 1,500 units of antitoxin routinely) it would seem better to use this as a minimum dose and adjust the dosage to the patient's need." Stafford [2h] would omit antitoxin entirely in subjects who are sensitive to horse serum. He recommends keeping such patients under close observation and starting tetanus toxoid injections immediately.

Thus, there is no general agreement regarding the dose of antitoxin to employ in the prophylaxis of tetanus in the unimmunized individual. Indeed, there are those [41] who appear to doubt that the usual dose of prophylactic tetanus antitoxin is efficacious at all. This nihilistic view is unjustified, and genuine evidence to support it is not presented. The observation cited by Stafford that, in Baltimore, tetanus has occurred just as often in patients given antitoxin prophylaxis as in those not so treated is actually uninterpretable, since there is no information on the proportion or the severity of injuries for which antitoxin was given. Furthermore, aside from the World War I experience,[15] there is ample experimental evidence, dating back many years, that antitoxin prophylaxis can prevent the occurrence of tetanus in experimentally infected animals.

Assuming that prophylactic antitoxin is indicated in a given situation, what dose will provide virtually certain protection, without unduly increasing the incidence of serum sickness and the risk of other serum reactions? This question cannot be answered on the basis of experience in man. In any case, the answer will vary with the type of injury, the feasibility of adequate débridement, the interval since injury, and the immunological status of the patient with respect to horse serum. Thus, it is impossible to predict correctly the patient in whom 1,500 units of antitoxin will fail to give protection. Therefore, when the administration of antitoxin is clearly indicated, it is logical to advocate larger doses as a routine measure. Increasing the dose of antitoxin given to a normal patient will somewhat accelerate the appearance of antitoxin in the circulation and will increase the duration of the protection, so that the risk of fulminating tetanus or late tetanus—the two most likely causes of failure to protect with a small dose of antitoxin—will be diminished.

On the other hand, in a patient who possesses antibodies against horse serum (the type of person who characteristically manifests accelerated serum sickness), an increase in the dose of antitoxin given may not materially prolong its effectiveness. Confirming the classic observations of von Pirquet and Schick and of Rackemann and Longcope, Mahoney and Moloney[42] have shown that, in general, tetanus antitoxin disappeared from the circulation more rapidly in patients who had serum sickness than in those who did not exhibit this complication. Nevertheless, as a general rule, an increase in the dose of prophylactic antitoxin is definitely indicated if there has been delay in treating the wound, if the injury is difficult to débride and decontaminate, or if there is massive contamination of necrotic tissue. In such cases, the prophylactic administration of penicillin may be of some value. However, it must be remembered that penicillin is no substitute for specific prophylaxis and adequate débridement of the injury. The final decision must be made by the physician, who must balance his estimate of the risk of tetanus in the patient against the immediate, as well as the possible ultimate, consequences of administering antitoxin.

Since failures to protect a patient with 1,500 units of antitoxin have been recognized for over 40 years, why was not the recommended prophylactic dose increased long ago? The answer probably lies in the fear of serum reactions, not merely serum sickness, which is well known to increase in frequency with larger doses of serum, but also the danger of more serious complications such as neuritis, myelitis, periarteritis nodosa, deafness, pericarditis, myocarditis, encephalopathy, or fatal anaphylactic shock. However, the very general adoption of enzyme-purification methods has led during the past 20 years to the production of antitoxin of greater purity and a lower incidence of serum sickness than formerly.[43] With such improved methods available, there should be less hesitation in giving as much antitoxin as the physician's judgment of the tetanus hazard indicates. Nevertheless, the limitations in the effectiveness of increasing the dose and the hazards that accompany the administration of serum should always be borne in mind.

In my opinion, when prophylactic tetanus antitoxin is medically indicated, 3,000 to 5,000 units should be an adequate dose in patients over 10 years of age if seen on the day of injury, except in the case of compound fractures, gunshot wounds, or other wounds not readily débrided. Delay of more than one day or the presence of complications such as those cited would indicate a dose of 6,000 to 10,000 units or more, depending on the circumstances of the individual case. Half of the stated dose should suffice in children under 10 years of age.

Active-Passive Immunization in the Unimmunized Subject.—The physician who is obliged to administer tetanus antitoxin to a patient because active immunization was never instituted will naturally want to obviate such an event occurring in the future, especially since reinjection of antitoxin is not only more likely to cause an untoward reaction but is likely to be more transient in its effect. Thus, it is logical to institute active immunization in patients who have received prophylactic antitoxin.

It has often been advocated that such patients be given tetanus toxoid at the same time as antitoxin, thus starting the patient on a course of immunization which, once having begun, he is presumably more than likely to finish. This procedure was recommended over 30 years ago by Ramon and has been employed for the control of both tetanus and diphtheria. The data on its effectiveness as regards tetanus are not explicitly clear. There have been several studies on this point in animals but few in man. Gold and Bachers[44] reported that the simultaneous administration of alum-precipitated tetanus toxoid to individuals given 1,500 units of antitoxin, followed by a second dose of toxoid two to three months later, led to a normal and adequate immune response in these individuals. When fluid toxoid was employed, three doses were essential to elicit a satisfactory antitoxin level. On the other hand, Huber[45] found that, with two doses of precipitated toxoid given 18 days apart, the response was not fully satisfactory when the first dose was given simultaneously with 1,500 units of prophylactic antitoxin. Hence, a third dose given some time later was indicated if active immunization was to be successfully instituted. Thus, although it is possible to institute simultaneous active-passive immunization with precipitated toxoid and 1,500 units of antitoxin, the results do not appear to be as reliable as those obtained with toxoid alone. Stated differently, these studies suggest that, if active-passive immunization is employed, three doses of toxoid should be given in order to achieve satisfactory results. Moreover, if large doses of antitoxin are administered, simultaneous active-passive immunization is apparently impractical,[46] and initiation of active immunization must definitely be delayed for several weeks; the waiting period depends on the amount of antitoxin given. In other words, the procedure of active-passive primary immunization may be employed when psychological or other circumstances warrant it, but it cannot be definitely relied upon unless no more than 1,500 to 3,000 units of antitoxin are given, and unless three doses of toxoid are included in the basic schedule. Fluid toxoid appears to be less efficient for this purpose.[17]

Summary

Active and Passive Immunization.—Passive immunization against tetanus provides immediate but transient protection against tetanus. In contrast, active immunization with toxoid leads to a slowly developing but long-lasting immunity. Passive immunization has numerous disadvantages and has never, at its best, given as high a degree of protection as does active immunization. Hence the latter is the procedure of choice for the specific prophylaxis of tetanus, whenever time and circumstance permit it to be applied.

Use and Effectiveness of Tetanus Toxoid in Routine Immunization.—Tetanus toxoid is one of the most effective and innocuous immunizing agents known. Since all human beings are subject to some chance of contracting tetanus, all people should, ideally, be immunized with toxoid. In particular, high-risk groups and groups readily reached en masse should have such immunization as a matter of routine medical and health policy. Adequate immunization against tetanus may be achieved with a variety of separate or combined preparations. It is important to administer at least three doses of fluid toxoid or two doses of precipitated toxoid in order to establish acceptable primary immunization. "Basic immunization" may not be regarded as completed until an additional reinforcing dose is given, preferably 6 to 12 months after primary immunization. This reinforcing dose greatly enhances and prolongs the immunity established with primary immunization. Immunization of infants is readily accomplished, but, if the infant is born of an immunized mother, an extra dose of toxoid (or the appropriate combined vaccine) is recommended as part of the primary immunization. Such an extra dose is also recommended whenever there is specific indication for early achievement of a high and lasting level of immunity.

Immunity to tetanus, once established by adequate basic immunization, should be maintained at a protective level by periodic booster doses. The level of immunity falls, though very slowly, for years after basic immunization or reimmunization. Hence, it appears wise to administer booster injections at intervals of four to five years. Shorter intervals are not ordinarily indicated, especially since there is some evidence that repeated inoculations may lead to sensitization of the delayed type in a small proportion of patients. Longer intervals—up to 10 years or more—do not appear to decrease the capacity of the booster dose to elicit a response, but the rate of response may perhaps be somewhat slower.

A detectable rise in antitoxin level after a booster injection occurs in almost all subjects within five days and sometimes sooner. There is some evidence, though not unanimous agreement, that fluid toxoid elicits a slightly more rapid response than does precipitated toxoid.

Management of Patients with Tetanus-prone Injuries.—The prevention of tetanus after an injury is dependent first upon adequate surgical care of the injury, with emphasis upon débridement and exposure of the injured area and removal of foreign material. Specific prophylaxis with tetanus toxoid will be of incontestable value if the patient has a known reliable history of primary immunization within five years or of primary immunization plus reinforcing or booster doses at any time. Prompt injection of tetanus toxoid in such patients will give adequate protection against tetanus in practically all cases. However, simultaneous injection of 1,500 units of antitoxin, at a different site, may be considered for patients with clearly tetanus-prone injuries under conditions of exceptional risk, such as a delay of more than 24 hours in treating a massively contaminated or deeply penetrating injury, an interval of over 10 years since the last injection of toxoid, or, in intermediate situations, a combination of delay in treatment and severity of injury. The combined use of toxoid and antitoxin, in those few situations in which it is indicated, will minimize the risk of fulminating tetanus during the interval prior to the appearance of the booster response to tetanus toxoid. This advantage is to be balanced against the hazard or inconvenience of a possible reaction to the antitoxin.

The long persistence of protective residual antitoxin titers after a booster dose will serve to prevent many cases of tetanus arising from trivial or unrecognized injuries and will render unnecessary the repetition of successive emergency booster injections of toxoid at close intervals, except when the risk of massive tetanus infection is apparent.

In patients without a valid history of adequate tetanus toxoid immunization, tetanus antitoxin must be employed for emergency prophylaxis of tetanus-prone injuries. The customary dose of 1,500 units does not give entirely reliable protection, and a dose of 3,000 to 5,000 units is recommended when prophylaxis of tetanus is medically indicated. This dose should be increased if complete débridement is impractical or if significant delay has occurred in treating the injury.

The unimmunized subject should be immunized as soon as practical. It is possible to begin active immunization at the same time as prophylactic antitoxin is given, but the procedure is effective only if the dose of antitoxin is relatively small and if an extra dose of toxoid is included in the primary immunization schedule. Precipitated toxoid is preferable to fluid toxoid for this purpose.

Because of space limitation the references will be published in the author's reprints only.

NEW DATA ON MORBIDITY FROM CANCER

FINAL analysis of valuable new data on cancer in the United States appears in a monograph published by the United States Public Health Service.[1] The basic data were obtained in a survey begun in 1938 by the National Cancer Institute, and they relate to 10 metropolitan areas. The study of intercity differences therefore is possible. The 1937-1938 morbidity study of the 10 cities was published in 1944.[2] Since two decades have elapsed from the time the survey began, it is possible to examine the data for secular trends.

Preliminary study of the basic data showed that office patients were much less likely than hospital patients to have the diagnosis of malignancy verified by histological examination of biopsy or autopsy material. The relation of socioeconomic status to the incidence of cancer in various sites is one significant feature of this study. The difference between office and hospital patients and the fact that the percentage of patients who do not go to a hospital varies greatly in different parts of the country were duly taken into account in interpreting the results. This is but one illustration of the complexity of a problem which was investigated with great care.

After corrections for age, the incidence rates for male and female were found to be essentially equal, but striking differences were found between races and among the various age groups. Outstanding, perhaps, is the increased susceptibility of older persons, so that by age 90 the chance of developing cancer is 200 times that at ages 5 to 15 years. For cancer of the lung, urinary bladder, stomach, and prostate, no consistent differences appeared in the age distributions of cases when classed by stage of disease at diagnosis. It was not certain that cases first diagnosed at time of death or after remote metastases had developed could have been diagnosed at an appreciably younger age. This agrees with the results of a study in Connecticut which showed little progress in the early recognition of cancer in inaccessible sites and revealed that in the case of cancers of the digestive system the percentage diagnosed while still localized was actually less in 1947-1951 than it had been in 1935-1940.[3] This is significant in view of the current assumption (and hope) that the early diagnosis of cancer increases the likelihood of successful treatment.

Another common assumption is that mass screening programs, periodic health examinations, and alertness on the part of patients and physicians will increase the likelihood of early diagnosis and so increase the likelihood of successful treatment. Here the analysis becomes extremely difficult. The results again are not encouraging, for the data do not lend any sound support to either assumption. One is reminded of a statement made eight years ago that "It has not been proved that the survival rate of cancer of the breast, using the 5-year survival rate as an index, is affected by treatment at all."[4] A similar conclusion was reached in a recent study of 230 cases of untreated breast cancer by Philipps, who found that the survival rate calculated from onset of symptoms was consistently higher for treated patients but that the differences were not significant.[5]

The new data are also analyzed with respect to some geographical factors. While statistical data usually answer only the questions they are designed to answer, when they are classified geographically it is always possible that sharp regional differences might lead to the recognition of some peculiarity of soil, weather, flora, fauna, food, occupation, or social patterns of fundamental significance. In the present analysis no fresh clues as to the etiology of cancer are uncovered. The present investigation is outstanding for the breadth of its scope and the care with which the results have been interpreted. Paradoxically, much of its value is in some of the negative conclusions to which it leads. This helps to clear the way for work in other directions. The need for continued research could not be more pressing.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

"Doctor, I have been named to my local society's grievance committee. But I am not going to serve. I see no reason why I should be put on the spot, taking abuse from patients and colleagues who don't like the committee's decision."

This is part of an actual conversation I had recently with a physician during a stopover in the Midwest. I disagreed with the doctor for several reasons and I enumerated them to him like this:

First, I believe that participation in local and society affairs definitely helps to make an individual a better physician in the community. For example, if each of us were to serve a two, three, or four year term on a grievance committee, I am convinced that we would gain a great deal of understanding and knowledge of patients and ourselves.

Second, I do not believe that patients or colleagues resent fair and reasonable decisions that are rendered after careful and thorough considerations of both sides of a grievance.

And third, the grievance committee is a valuable service performed by the medical society for the public and for the profession. The resolving of grievances is our responsibility to patients. If by our indifference and disinterest we fail the public, then an outside agency or authority is certain to be brought in to assume our functions—no matter how rightfully they now belong to us.

Let's remember, too, that the grievance committee protects the ethical practitioner as well as guarding against the unethical physician. Just as the grievance committee will condemn the exorbitant fee and the unnecessary medical procedure, so it also will exonerate the good doctor against the indiscriminate and groundless accusations of the "griper" and the complainant who demands the most from his physician but who often wants to pay little or nothing.

This kind of protection to its medical society members is a responsibility of the grievance committee. On the other hand it is only proper and necessary that all physicians in the society cooperate with the committee. They must present data to the committee when requested and must appear before the committee when asked. To do less is to erode the usefulness and effectiveness of the grievance committees.

The committee, of course, has certain responsibilities to the physicians and the patients who are parties to the alleged grievance. It must not think that a grievance is too complicated. All the facts must be gathered. It must not postpone a decision, hoping that delays might "kill" the grievance.

Members also must be straightforward in their approach, reviewing the case objectively. To allow personalities to enter the case or the decision is a disservice to the patient, to the physician, and to the entire medical profession.

Service on a grievance committee is not for the mushmouths, the spineless, or the mindless. Membership requires an ability to call the shots as one sees them.

In my opinion it would be unfortunate if even one of our more than 1,100 grievance committees were to be turned into a "whitewash" committee. But if physicians are apathetic and indifferent to their service or their duties on the committee, then I am afraid we are in for a good deal of justified criticism.

Selection to serve on a grievance committee is to me a distinct honor. To reject it out of fear of what someone might say is bad enough; to accept it and serve without interest and vigor is a real tragedy.

Louis M. Orr, M. D.
Orlando, Fla.

ORGANIZATION SECTION

STATEMENT TO INTERSTATE AND FOREIGN COMMERCE COMMITTEE ON S. 1283

August 13, 1959

Senator Warren G. Magnuson, Chairman
Interstate and Foreign Commerce Committee
United States Senate
Washington 25, D. C.

Dear Mr. Chairman:

We have been advised that your Committee is currently conducting hearings with respect to S. 1283, 86th Congress, a bill to regulate the interstate distribution and sale of packages of hazardous substances intended or suitable for household use. I would like to request that this letter, which outlines the position of the American Medical Association, be inserted in the record of the hearings.

Uniform legislation to require precautionary labeling of all chemical products containing hazardous substances has been an objective of medical and health groups for nearly a century. Over 75 years ago, the American Medical Association adopted a resolution urging Congress and the various state legislatures to enact legislation to require lye to be sold as a poison and under a poison label. Later resolutions were adopted in 1910 and 1918 urging the proper labeling of caustic poisons. These actions culminated in the formation of an Association Committee, under the Chairmanship of Dr. Chevalier Jackson, a noted otolaryngologist of Philadelphia, to obtain legislation regulating the sale of caustic products.

In 1923, the House of Delegates of the American Medical Association adopted a resolution which called attention to the fact that the domestic use of concentrated lye and other caustic alkalies and corrosive substances was a recurring cause of death and distressing disability among children. It recommended, in the interest of public health and safety, that the packing, labeling and distribution of such substances be regulated by law. The Association Committee thereafter prepared a model state law and a bill for introduction in Congress. The Federal Law was enacted in 1927, and the model state bill has been enacted in a number of states.

Since that time many new compounds for household, commercial and industrial use have been introduced which are not covered by the above mentioned legislation. Presently, there is no broad law which requires the precautionary labeling of hazardous substances at the national level. Various attempts have been made in recent years to extend the scope of existing legislation to require precautionary labeling of potentially harmful chemicals in commerce. The first of these attempts was the Bingham bill of 1932 which called for the labeling of certain chemical products, particularly those evolving injurious vapors. This bill served to focus attention on the need for a sustained, dynamic program for the development of precautionary labeling for hazardous chemicals.

Several years ago, at one of the periodic meetings of the American Medical Association's Committee on Toxicology with various chemical industry groups, a recommendation was made that the AMA consider the development of model legislation to require precautionary labeling of household and industrial chemicals not so regulated. The Committee was subsequently authorized to undertake this task and has spent two years surveying existing legislation, reviewing various labeling schemes proposed in this country and abroad, and consulting numerous associations and qualified authorities. This study has revealed the need for:

(1) A broad and encompassing label law as a weapon in any successful attack on accidental poisoning from harmful chemicals. Lack of information about hazardous ingredients in cases of poisonings have enhanced their gravity by complicating or delaying treatment.

(2) Directing such a law toward the reduction in careless handling and storage of potentially harmful products, which are found in and around the house, in small businesses, and in other areas where the control of exposure to chemicals is not as guarded as in the manufacturing process. The law should require informative labeling, which would include a list of hazardous ingredients, their potentialities for harm, directions for safe use, and first-aid instructions.

(3) Similar labeling standards for chemicals for export to foreign countries, thereby obviating the recurring complaint that less-than-standard products are sold to foreign purchasers.

(4) Label warnings based on the anticipated degree of danger and the use of words and symbols that facilitate recognition. In practice, however, few persons are sufficiently interested or informed to analyze the precise shades of meaning given to the signal words such as "danger," "warning" or "caution" and thereby act accordingly. Therefore, consideration should also be given to the use of familiar warning symbols such as a flame for inflammable substances or a skull and crossbones for very poi-

sonous substances because they are readily recognized and meaningful even to the illiterate. The use of carefully chosen symbols in conjunction with the signal word "danger" for substances presenting the greatest hazard would facilitate recognition and bridge the language barrier.

In this connection, the following modifications of S. 1283 are recommended in order to provide adequate protection for the user of such products in the home or at work:

(a) Extend the scope of the bill to apply to all hazardous substances "distributed as packaged chemicals for non-manufacturing purpose" rather than simply to those "intended or suitable for household use."

(b) Require the same labeling for chemicals exported to foreign countries as those for domestic consumption by deleting the word "not" on line 1 page 11.

(c) Include appropriate warning symbols (safety pictographs such as the skull and crossbones) to various types of hazard (i. e.—flammable, explosive, poison) associated with the more dangerous products. In this connection, the Committee's attention is invited to the warning symbols adopted by the International Labor Organization and the United Nations for explosive, flammable and poisonous materials.

On behalf of the American Medical Association, I would like to thank you for the opportunity of presenting our position with respect to S. 1283, 86th Congress.

Sincerely,
F. J. L. Blasingame, M.D.
Executive Vice-President

DR. TALBOTT APPOINTED EDITOR OF THE JOURNAL

The Board of Trustees has appointed Dr. John H. Talbott, professor of medicine at the University of Buffalo School of Medicine and physician-in-chief at Buffalo General Hospital, as Director of the Division of Scientific Publications and Editor of The Journal.

Dr. Talbott was born in Grinnell, Iowa, in 1902, and received his medical degree from Harvard Medical School in 1929. He interned at the Presbyterian Hospital, New York, then returned to Harvard and to the Massachusetts General Hospital in 1931, serving, except for five years in military service, in teaching and clinical positions until 1946, when he became physician-in-chief at the Buffalo General Hospital. He did postgraduate work at the University of Göttingen, Germany, in 1932, and at the University of Innsbruck, Austria, in 1937. He was a member of an International High Altitude Exposition to South America in 1935 and a member of a team that studied the frostbite problem among U. S. troops in Korea in 1951. For 11 years he has been editor of *Medicine,* a quarterly journal devoted to advances in research in medical science. Commissioned in the U. S. Army Medical Corps in World War II, he served as chief of laboratory services at the Sixth General Hospital and as commanding officer of the Climatic Research Laboratory at Lawrence, Mass., for which services the Legion of Merit was awarded.

Dr. Talbott will take over his new duties about October 20, succeeding Dr. Johnson F. Hammond, who for 37 years has been on the staff of The Journal as news editor, assistant editor, associate editor, and editor, except for three years during World War II when he served in the Surgeon General's Office to organize and edit the *Bulletin of the U. S. Army Medical Department,* for which service the Legion of Merit was awarded. Dr. Hammond will continue his service on The Journal as Editor Emeritus.

STATEMENT OF DR. FREDERICK C. SWARTZ TO THE SUBCOMMITTEE ON PROBLEMS OF THE AGED AND AGING

SENATE LABOR AND PUBLIC WELFARE COMMITTEE

August 5, 1959

Mr. Chairman and Members of the Subcommittee:

I am Dr. Frederick C. Swartz of Lansing, Michigan, Chairman of the American Medical Association's Committee on Aging. The medical profession applauds the Senate's concern with the aged and aging and the way in which this subcommittee is going about its work. It is commendable that you have set out to gather all available facts before seeking any conclusions. Your approach to this complex subject is similar to our own. We too have been after the facts since 1955, when the A. M. A. first appointed its Geriatrics Committee and charged it with the responsibility of studying the diseases of the aged.

We quickly realized that there are practically no diseases of the aged. There are simply diseases among the aged, which is a far different thing. We concluded, therefore, that the real area of our concern was more properly the health of the aged and aging. The Geriatrics Committee was renamed the Committee on Aging, and ever since, every aspect of living which bears directly or indirectly on the health of our older people has been under our intensive study. Good health is far more than the mere absence of disease or infirmity. This is only its negative side. Health is also the positive state of physical, mental, and social well-being, and any factor which detracts from that well-being detracts from the individual's total health.

Loneliness, rejection, and lack of useful things to do affect the general health of the aged. Hardening of the arteries is certainly no worse than softening of the will to live. This applies to every human being, but particularly to the aged. The older person wants just about the same things that the rest of us do: to be part and parcel of his environment; to be loved; to belong; to feel that his skills and talents have value, and that they will be used and appreciated. These are the fundamentals. We are, however, prone to forget them when we discuss the problems of the aged. We tend to talk in terms of medical need. We forget that medicine does not function in a vacuum but in the context of a society. In that context, medicine becomes only a segment of the broad spectrum of health in its broadest sense.

All of us—no matter who we are, what we do, or where we live—have definite responsibilities in regard to our elder citizens. We believe it is society's responsibility to stimulate, in older people, that intangible quality called the will to live. I have seen people with this quality survive illnesses against which they seemed to have little chance. I have seen people without this quality die long before they should. The will to live is the difference between fighting on and giving up—the difference between staying in the mainstream of life, active and interested, or becoming segregated and remote from life, a passive spectator who no longer cares. People who feel rejected, shunted to the sidelines by society, all too often lose the will to live. Medical and hospital care, important as they are, can never compensate for rejection. To stay alive and make their later years full and rewarding, old people must care, but they will not care unless we make it plain that we want them to care because we care about them—that we value their wisdom and experience and are anxious to use it.

We believe that it is society's responsibility to encourage our elders in their desire to be self-reliant, to maintain faith and pride in themselves. Most of these people don't want to be the wards of anyone. They want a helping hand if needed, but not a handout. Anything that undermines the self-respect of a man or woman undermines health and saps the will to live. I know of an elderly woman, plagued with all sorts of physical problems, who repeatedly urged the son with whom she lived to accept part of her own limited income for household expenses. The son neither wanted nor needed the money, but he finally agreed. It wasn't at all important to him, but it was important to her. She felt she had regained her self-respect. Her health improved accordingly.

We believe it is society's responsibility to assist older people in their desire to be treated as individual persons, each with different physical chemistry, different hopes, different needs. The 15 million persons we are talking about are alike in only one way: they are all 65 years of age or older. They are not a homogeneous group. They have no uniform list of wants that can be met by some convenient, all-encompassing master plan. They are individual persons, and we must always remember it. Many work at the old job still—some because they want to, others because they must. Many have retired—some because they had to, others because they wanted to. Many are finding a life rich and deeply satisfying. Others are ready to throw in the sponge. The point is that all of them are different.

Moreover, we believe that it is society's responsibility to encourage our elder citizens in their desire to be useful. Actually, this is more than a desire: It is a right. The right to be useful should be just as inalienable as the right to dissent or any other right. Somewhere, someone, sometime, decided that the age of 65 years was old. It was as unsound a judgment as it was arbitrary, but once uttered, it was the first step to the conclusion that 65 was too old, and the idea spread. As ridiculous as it seems, numberless Americans now believe that 65 candles on the birthday cake disqualify a man for anything better than baby-sitting, whittling, or sleeping in the sun. This is shockingly evident in the field of employment, where a man's right to be useful is frequently abridged by compulsory retirement policies.

Many of the same firms that hire so carefully, taking into account the person's training, skills, attitudes, and potentials, find nothing inconsistent in the retirement of a valuable employee by a chronological rule of thumb. This is a case where no one benefits—neither the employer nor the worker compelled to retire. Most of our older people want to work and need to work, and good employees are not easy to replace. Retirement is fine for those who want it, but age should not be the determining factor. Some men are old at 50. Others are vigorous and capable at 75. Personnel policies should be flexible enough to take this into account and to use the yardstick of ability instead of the yardstick of age.

It may not seem that the matter of compulsory retirement has much to do with health, but I can assure you, as a physician, that it does. A man who has spent a quarter of his life learning to become independent, and a half of his life being independent, is suddenly cut off from his work. Suddenly he has been denied the right to be useful. Unprepared for the sudden change in status, he finds himself at loose ends, burdened by a leisure he hasn't learned how to use. All at once he notices a subtle change in the attitude of his family, of his friends, of his community. He is no longer the breadwinner. He has become overnight a man who no longer works for his living, a man whose time hangs heavily on his hands, a man whose stature has mysteriously diminished.

To compensate for that which he has lost, he often develops aches and pains, and whether some of them are imaginary or not, he suffers just the same. The doctor who treats this man is faced with a sociological as well as a medical problem. Physicians have yet to find an antibiotic for loneliness or rejection. We must, therefore, think of the medical challenge as only a segment of the total challenge. While the physician practices preventive medicine and seeks to forestall the disabling illness which can cripple an older person, society must also take the necessary steps to meet the other existing needs that are just as important. Society must, through education, prepare people for retirement and old age. It must think in terms of the older person's many other requirements, whether they be in housing, recreation, or community understanding. Until society recognizes this fact, we will be taking a piecemeal, hit-or-miss approach to a problem that demands a broad-spectrum solution.

In much of the world no challenge is posed by a large number of old people. In much of the world they just don't get old. They die young. Thank God we in America have the "problem" of 15 million Americans who constitute one of our greatest assets, and thank God an increasing number of persons and groups have accepted the challenge and are beginning to meet it. The medical profession, together with the many others who work in the field of health, is proud of having increased the life span of the average American. This increase in years has been accompanied by a rise in health levels for all ages, including those over 65. It is the responsibility of all our citizens to work together to insure that the lives we have helped prolong are as satisfactory in their later years as they were in youth.

I promise you, gentlemen, that the American doctor will do his part and more, but the answers that must be found and the solutions that must be reached involve every segment of our population: every profession, occupation, industry, labor organization, religious denomination, civic group, community, and—most important of all—every family unit. All must share the common responsibility.

I am proud that the solutions are being found, that real progress is being made through the cooperative efforts of private citizens. Working voluntarily, they are proving their ability to do the job in their own communities—and do it effectively and well. A few specifics from their record of accomplishment are appended to this testimony. The medical profession has continued in its role of providing leadership and support to the general voluntary effort. At this time it is enough to say that retirement villages, new nursing homes, chronic disease care centers, home care programs, recreational facilities, and research projects are being set up from coast to coast in substantial number, and many more are on the way.

Our state and local medical associations have moved promptly to make the American Medical Association's six point program, which I discussed with this subcommittee in June, an effective and workable instrument. The medical needs of the aged involve the chronic illnesses and the so-called degenerative diseases. In a large percentage of patients the main need is not for an expensive hospital stay or a surgical operation, but for medical care at home or in the doctor's office. In others, the important requirement is nursing care in the patient's home, or the home of relatives, and in still others, custodial care in a nursing home or public facility may be the only answer. The point is that the medical needs of this particular segment of the population are subject to countless variations.

Wherever possible, we try to keep our older patients out of institutions and functioning in society. Our object is to help them lead lives as normal as possible—lives which will minimize their dependence. This means that we want them to have easy access to medical and hospital services, adequate and suitable housing, specialized and personal services, and sources of rehabilitation where needed. We are working to reduce the cost of services, which calls for new and improved facilities specially tailored to the particular requirements of the older citizen. The A. M. A. has therefore supported a government-insured loan program of the F. H. A. type for nongovernmental hospitals and nursing homes, whether of a nonprofit or proprietary nature. It has recommended changes in the Hill-Burton Act to help the individual states earmark more money for nonprofit nursing homes.

The A. M. A. continues to back further experiments with progressive hospital care, home care programs, and homemaker services, all of which have the common purpose of reducing the length of hospital and nursing home confinement by allowing the earlier discharge of patients. To encourage the trend to private health insurance, the A. M. A. House of Delegates adopted a proposal which applies specifically to those over 65 with modest resources or low family income. In this proposal, the A. M. A. urged physicians to set their fees at a level which will permit the development of insurance and prepayment plans at a reduced rate. The reaction, by state and local medical associations, has been heartening.

There are now 25 plans in 23 states in which Blue Shield plans enroll those over 65, and all Blue Shield plans now permit persons over 65 to continue their coverage. Further, in almost every other state in the country, our medical societies, in cooperation with the plans they sponsor, are working out programs of a similar nature. We believe the solutions we seek are to be found in private and voluntary action at the community level, and in private health insurance and prepayment plans which have made revolutionary progress since World War II and are still increasing their gains. At the end of 1945, only 32 million people were covered under such voluntary programs; but by the end of 1958, the number had soared to 123 million. Putting it another way, fewer than one

American out of three had health protection in 1945, yet today, the figure is nearly three out of four.

This is important, for it indicates that prepayment plans and the health insurance industry, by providing more and expanded health coverage for all age groups, are anticipating and solving tomorrow's health care financing problem. Each year, more and more of the Americans who are reaching 65 are covered. The problem of financing health services for the aged is therefore a temporary, not a permanent one. Dozens of different type policies are now available. Among them are policies guaranteed renewable for life; policies to cover those over 65; coverages that will continue after retirement; and group policies that may be converted to individual coverage on termination of employment.

According to the Health Insurance Association of America, 60% of our senior citizens who need and want health insurance will have protection by the end of next year. Further, that percentage will increase until 75% will be covered in 1965, and 90% in 1970. In other words, the problem of financing the health care of our older people is being met by private insurance and prepayment plans; and the particular hospital and medical needs of the aged are being met by voluntary effort, by private citizens, at the community level. The health professions and the communities are doing the job—a job they know and understand.

Dr. Michael M. Dasco, director of physical medicine and rehabilitation at New York's Goldwater Memorial Hospital, recently expressed in *Life* magazine an opinion with which I thoroughly agree. He said:

> In our society, the responsibility for taking care of the old person rests primarily with his family. If the family cannot fulfill this responsibility, then it passes to the community, then to the state. Only as a last resort should the federal government step in.

A sage but unknown author summed up most effectively the point that age is relative when he wrote:

> Youth is not a time of life. It is a state of mind. It is a temper of the will—a quality of the imagination—a vigor of the emotions. Nobody grows old by merely living a number of years. People grow old only by deserting their ideals. Years wrinkle the skin, but to give up enthusiasm wrinkles the soul. Worry, doubt, self distrust, fear and despair—these are the long, long years that bow the heart and turn the greening spirit back to dust. Whether sixty or sixteen, there is in every human being's heart the lure of wonder, the undaunted challenge of events, the unfailing child-like appetite for what next, and the joy of the game of living. We are as young as our self-confidence, as old as our fear; as young as our desire, as old as our despair.

I should like to thank the members of this subcommittee for the opportunity of expressing some of the views of the medical profession on the problems of the aged and aging. I shall be glad to attempt to answer any questions you may have.

GOVERNMENT SERVICES

FEDERAL AVIATION AGENCY

Personal.—The following key appointments in the office of the civil air surgeon were made: Dr. John E. Smith, chief, research requirements division; Dr. Homer L. Reighard, chief, medical standards division; Dr. James H. Britton, chief, medical certification division; Dr. Paul T. Bruyere, chief, standards evaluation branch; Capt. Carl E. Wilbur (U.S.N.), chief, accident studies branch; and Major Wayne R. Otto (U.S.N.), chief, rules and procedures branch. These men will serve under the direction of Dr. James L. Goddard, recently named FAA's first civil air surgeon.

PUBLIC HEALTH SERVICE

Plan to Improve Mental Health.—Surgeon Gen. Leroy E. Burney appointed an *ad hoc* committee to develop a basis for improved planning of mental health facilities throughout the nation in response to a recommendation of state mental health authorities. The group will work with the Public Health Service in formulating therapeutic and administrative guidelines which can be used in developing statewide plans for mental health facilities. In the past, emphasis was placed on providing large institutions for the care of the mentally ill. Services now being developed include outpatient and emergency service through hospital clinics or mental health centers and increased use of general hospitals for the treatment of psychiatric patients, halfway houses, and nursing homes.

The committee, to meet in Washington, D. C., Oct. 12 and 13, includes Dr. John J. Bourke, executive director, New York Joint Hospital Survey and Planning Commission, Albany; Dr. Bernard Bucove, director, Washington State Department of Health, Seattle; Dr. Dale C. Cameron, director, division of medical services, Minnesota State Department of Public Welfare, Minneapolis; Dr. R. L. Cleere, director, Colorado State Department of Public Health, Denver; Dr. Terrell O. Carver, administrator, Idaho Department of Health, Boise; Dr. Hiram W. Davis, commissioner, Virginia State Department of Mental Hygiene and Hospitals, Richmond; Herbert G. Fritz, chief, division of hospitals, Maryland State Department of Health, Baltimore; Dr. Stewart T. Ginsberg, commissioner, division of mental health, Indiana State Department of Health, Indianapolis; Dr. Jack C. Haldeman, chief, division of hospital and medical facilities, Public Health Service, Washington, D. C.; Dr. Robert T. Hewitt, chief, hospital consultant services, Community Services Branch, National Institute of Mental Health, Bethesda, Md.; Mrs. Louise Waagen Masters, director, division of hospital facilities, New Mexico Department of Public Health, Santa Fe; and Dr. Harold L. McPheeters, commissioner, Kentucky State Department of Mental Health, Louisville.

COUNCIL ON NATIONAL DEFENSE

MEDICAL CIVIL DEFENSE CONFERENCE

The Council on National Defense, American Medical Association, is sponsoring the 10th annual conference of the County Medical Societies Civil Defense Organization. The conference will be held at the Morrison Hotel, Chicago, on Nov. 7-8, 1959.

Program

These yearly conferences are planned to inform and otherwise assist medical and health personnel for their respective roles in disasters. Conferees have the opportunity (1) to participate in workshop sessions concerning medical preparedness to cope with disasters, (2) to discuss and exchange information dealing with emergency medical services, (3) to be informed on the availability of pamphlets and articles devoted to the medical and health aspects of civil defense, and (4) to hear outstanding speakers report on appropriate civil defense and disaster topics.

On the afternoon of Dec. 1, 1958, fire broke out in Our Lady of the Angels' school in Chicago. There were 95 deaths and several hundred school children were casualties. Three months later, a tornado hit St. Louis. The toll was several fatalities, 300 casualties, and extensive property damage. Disasters like these are constantly testing our individual and community stamina. They test our civil defense preparedness. There is no better way, short of war, to determine the operational capabilities and adequacy of medical civil defense planning.

Two reports at the conference will discuss the hospital and medical disaster programs in operation during the school fire and tornado.

A highlight of the conference will be a talk by Congressman Melvin Price on the environmental and biological effects of nuclear warfare. Recent hearings conducted by a Joint Congressional Atomic Energy Subcommittee assumed that a hypothetical attack produced 48,900,000 deaths. In spite of the tremendous number of deaths and staggering number of casualties created by the attack, the one-week hearings ended with the conclusion that the nation could recover from such an attack and that protection measures are feasible and could greatly reduce the casualties. Congressman Price is a member of the Joint AEC Committee.

What you should know about chemical and biological warfare will be one of the topics discussed at the conference. Major Gen. Marshall Stubbs, Chief Chemical Officer of the Army, is the speaker on this subject. As a result of testimony by leading military experts on CB warfare possibilities, the House Committee on Science and Astronautics recently issued a lengthy report recommending an increase to about 125 million dollars a year for research in this field by the Army Chemical Corps and a program to broaden public understanding of the dangers and uses of CBR agents.

Registration and Reservations

The conference group is self-supporting. As in the past, a registration fee is charged to defray the costs of the two luncheons and other administrative expenses of the conference. The registration fee is $10. Those planning to attend the conference are urged to mail their registration cards and fees promptly. The Morrison Hotel, 79 W. Madison St., Chicago, has set aside a block of rooms for the convenience of conferees. Individuals are urged to write directly to the hotel for reservations, making mention of the conference. Those desiring additional information about the conference are requested to contact Mr. Frank W. Barton, Secretary, Council on National Defense, American Medical Association, 535 N. Dearborn St., Chicago 10.

SATURDAY—NOV. 7, 1959
SOUTH CONSTITUTION ROOM, MORRISON HOTEL

8:00- 9:00		Registration—1st Floor Foyer
9:00- 9:05		Call to Order CARL J. SPRUNK, M.D.
9:05- 9:15		Welcome Address FRANKLIN D. YODER, M.D.
9:15-10:55		Civil Defense in the Federal Government
	9:15- 9:35	(a) The OCDM Program LEWIS E. BERRY
	9:35- 9:55	(b) Medical and Health Activities—OCDM W. PALMER DEARING, M.D.
	9:55-10:15	(c) The U. S. PHS Program CARRUTH J. WAGNER, M.D.
	10:15-10:35	(d) The VA Program WILLIAM S. MIDDLETON, M.D.
	10:35-10:55	(e) Military Assistance for Civil Defense Capt. HENRY T. GANNON, MC, USN
10:55-11:10		Break Period
11:10-11:40		Congressional Review of Environmental and Biological Effects of Nuclear Attack Honorable MELVIN PRICE
11:40-12		Operation of Small Hospital During Chicago School Disaster J. E. SEGRAVES, M.D.
12:00-12:30		Disaster Education in Medical Schools STANLEY W. OLSON, M.D.
12:30- 2:00		Luncheon—North Constitution Room Civil Defense Fantasies and Realities GEORGE R. PRICE, Ph.D.

Members of the program committee are Carl J. Sprunk, M.D., Chairman, Francis C. Jackson, M.D., and Frank W. Barton.

2:00- 2:15 Assembly for Workshop Sessions—South Constitution Room

2:15- 5:00 Workshop Sessions
Conferees to divide into four groups to discuss specific medical and health CD topics. Summary written reports of the workshop sessions will be prepared and distributed to all conferees.
I—Organization and Utilization of Hospital and Auxiliary Hospitals for Civil Defense, Including Location and Use of 200-Bed OCDM Hospital—South Constitution Room
Group Leaders: W. Palmer Dearing, M.D. and John N. Hatfield
II—Practical Aspects of Radiation Hazards and Shelter Protection—Parlor B
Group Leaders: Justin J. Stein, M.D. and Harold C. Lueth, M.D.
III—Practical Aspects for Mobilization and Training of Medical and Health Personnel in Care of Mass Casualties—Parlor C
Group Leaders: Carroll P. Hungate, M.D. and Carruth J. Wagner, M.D.
IV—Provision for Nonmedical Utilities and Services in Disasters—Parlor D
Group Leaders: Frank F. Schade, M.D. and Curtis H. Lohr, M.D.

6:00- 7:00 Social Hour—North Constitution Room

SUNDAY—NOV. 8, 1959
SOUTH CONSTITUTION ROOM

9:00- 9:15 Training Medical Aides for Civil Defense
Charles L. Leedham, M.D.

9:15- 9:30 The CD Role of Pharmacists
(Speaker to be selected.)

9:30- 9:50 Errors in Civil Defense Thinking
E. A. Burkhardt, M.D.

9:50-10:10 Business Session
Carl J. Sprunk, M.D., Presiding

10:10-10:30 Collection and Transportation of Casualties and Positioning of Emergency Medical Aide Teams
Joseph R. Shaeffer, M.D.

10:30-10:45 Break Period

10:45-11:05 Management of Casualties in St. Louis Tornado
Curtis H. Lohr, M.D.

11:05-11:35 Are Full-time Disaster Coordinators Needed in Hospitals?
Yes—Francis C. Jackson, M.D.
No—John N. Hatfield

11:35-12:00 What You Should Know About Chemical and Biological Warfare
Major General Marshall Stubbs, U. S. Army

12:00- 1:30 Luncheon—North Constitution Room

1:45- 2:00 Generating Community Support for a Medical CD Program
Paul A. Slattery, M.D.

2:00- 2:20 Changing Concepts of Disaster Medical Management
Frank F. Schade, M.D.

2:20- 2:40 Getting Public Acceptance of Civil Defense
Bernard F. Hillenbrand

2:40- 3:00 Development and Implementation of Minnesota CD Plan
M. D. Tyson

3:00- 3:20 Disaster Program of Flying Physicians Association
Frank H. Coble, M.D.

3:20- 4:00 Selected Movies

4:00 Adjournment

PARTICIPANTS

Lewis E. Berry, Deputy Director, Office of Civil and Defense Mobilization, Washington, D. C.

E. A. Burkhardt, M.D., Chairman, Special Committee on Civil Defense and Catastrophe, Medical Society of the State of New York, New York.

Frank H. Coble, M.D., Chairman, Disaster Program, Flying Physicians Association, Richmond, Ind.

W. Palmer Dearing, M.D., Director of Health Services, Office of Civil and Defense Mobilization, Washington, D. C.

Henry T. Gannon, Capt., MC, U. S. N., Military Assistant for Planning, Office of Assistant Secretary of Defense (Health and Medical), Washington, D. C.

John N. Hatfield II, Assistant Administrator, Burlington County Hospital, Mount Holly, N. J.

Bernard F. Hillenbrand, Executive Director, National Association of County Officials, Washington, D. C.

Carroll P. Hungate, M.D., Member, Committee on Disaster Medical Care, Council on National Defense, A. M. A.; Member, Council on National Defense, A. M. A., Kansas City, Mo.

Francis C. Jackson, M.D., Member, Committee on Disaster Medical Care, Council on National Defense, A. M. A., Pittsburgh.

Charles L. Leedham, M.D., Director of Education, Frank E. Bunts Educational Institute, Cleveland.

Curtis H. Lohr, M.D., Member, Committee on Civil Defense, Missouri State Medical Association, St. Louis.

Harold C. Lueth, M.D., Chairman, Committee on Disaster Medical Care, Council on National Defense, A. M. A.; Member, Council on National Defense, A. M. A., Evanston, Ill.

William S. Middleton, M.D., Chief Medical Director, Department of Medicine and Surgery, Veterans Administration, Washington, D. C.

Stanley W. Olson, M.D., Dean, Baylor University College of Medicine, Texas Medical Center, Houston, Texas.

George R. Price, Ph.D., Scientist, Writer, and Lecturer, New York.

Honorable Melvin Price, U. S. Congressman, 24th District of Illinois; Member, Committee on Armed Services and Congressional Joint Committee on Atomic Energy, Washington, D. C.

Frank F. Schade, M.D., Chief, Medical and Health Section, Los Angeles County and Cities Civil Defense Planning Board, Los Angeles.

J. E. Segraves, M.D., Director of Disaster Plan, St. Anne's Hospital, Chicago.

Joseph R. Shaeffer, M.D., Chairman, Committee on Disaster Surgery, Committee on Trauma, American College of Surgeons, San Antonio, Texas.

Paul A. Slattery, M.D., Co-Chairman, Disaster Committee, Alameda-Contra Costa County Medical Association, Orinda, Calif.

Carl J. Sprunk, M.D., Chairman, Medical Civil Defense Committee, Wayne County Medical Society, Detroit.

Justin J. Stein, M.D., Chairman, Committee on Military Affairs and Civil Defense, California Medical Association, Los Angeles.

Marshall Stubbs, Major Gen., U. S. Army, Chief Chemical Officer, Department of the Army, Washington, D. C.

M. D. Tyson, Civil Defense Coordinator, Minnesota Department of Health, Minneapolis.

Carruth J. Wagner, M.D., Chief, Division of Health Mobilization, Bureau of State Services, U. S. Public Health Service, Department of Health, Education, and Welfare, Washington, D. C.

Franklin D. Yoder, M.D., Director, Division of Socio-Economic Activities, American Medical Association, Chicago.

MEDICAL NEWS

ARKANSAS

Outbreak of Rabies.—The *Journal of the Arkansas Medical Society* for August reported that Arkansas is experiencing on outbreak of animal rabies. The principal areas involved are 13 counties in southwest Arkansas, south and west of the Ouachita River and about 12 counties in eastern and northeastern Arkansas. In addition, there are scattered cases of animal rabies in other parts of the state. As of May 30, 1959, a total of 130 cases of animal rabies were reported. This is more than twice as many cases for the same period of the previous year. The disease occurred in animals as follows: foxes 68, dogs 43, cattle 11, cats 5, mules 2, and skunk 1. The number of animal bites to people has likewise increased over the previous year. The number, as of May 30, reached a total of 468, as compared with 349 for the same period the previous year. Many of these animal bites occurred in children. The counties which gave completed dog vaccination programs reported 76,997 dogs as being vaccinated against rabies since Jan. 1.

CALIFORNIA

Camera for Three-Dimension Studies.—Stanford Medical School radiologists have installed an improved x-ray motion picture camera in a laboratory in the new medical center on campus. The apparatus films picture studies of the heart in three dimensions. Such studies are possible with the $100,000 device originally installed in the Stanford Hospital located in San Francisco. The project was financed by a grant from the National Heart Institute of the U. S. Public Health Service and by private gifts. A closed circuit television system will be incorporated into the unit for use in the new Stanford Medical Center.

ILLINOIS

Chicago

Celebrate Northwestern Centennial.—A founders day convocation, a medical sciences colloquium, and a centennial dinner will mark the centennial celebration for the faculty of Northwestern University Medical School, Sept. 29 in Thorne Hall, Chicago. Conrad Elvehjem, Ph.D., president, University of Wisconsin, will present "Science and Medicine" at the convocation, at which the following will receive honorary degrees of doctor of science: Dr. Charles Best, Toronto, Ontario; Horace W. Magoun, Ph.D., Los Angeles; Dr. Irvine McQuarrie, Oakland, Calif.; Dr. Joe Vincent Meigs, Boston; Dr. Isidor S. Ravdin, Philadelphia; Dr. William S. Tillett, New York City; Dr. Shields Warren, Boston; and Dr. Elvehjem. Six papers are scheduled for the medical sciences colloquium beginning at 2 p. m. At the evening dinner Horace W. Magoun, Ph.D., will present an address, "Concepts of Brain Function in Northwestern's Century."

KANSAS

Tubercular Mental Patients Go to Topeka.—Tubercular mental patients who had previously been cared for in small units at Osawatomie, Larned, and Topeka State Hospitals will all be treated at Topeka State Hospital in the future, according to a plan recently approved by the State Board of Social Welfare. Dr. Jaime Polit, tuberculosis control physician at the Osawatomie hospital, said the last group of patients from West Pavilion, the tuberculosis unit, left Osawatomie on Aug. 18. In all, eight patients from Osawatomie and 16 from Larned were moved to Topeka. Reports from the three mental institutions indicated a total of 34 patients in tuberculosis isolation in the three hospitals. It was decided that the number of such patients had been reduced sufficiently that their location in one facility was advisable, according to Dr. George W. Jackson, Topeka, director of institutions.

Southwest Clinical Conference.—The 37th annual fall clinical conference of the Kansas City Southwest Clinical Society will be held Oct. 5-8 in Kansas City. The program includes the following guest speakers:

Dr. William Dameshek, Boston; Dr. Richard J. Bing, St. Louis; Dr. Brian B. Blades, Washington, D. C.; Dr. Eugene M. Bricker, St. Louis; Dr. Edward A. Gall, Cincinnati; Dr. Keith S. Henley, Ann Arbor, Mich.; Dr. Richard H. Marshak, New York City; Dr. George G. McHardy, New Orleans; Dr. William T. Moss, Chicago; Dr. Edward S. Orgain, Durham, N. C.; Dr. Oglesby Paul, Chicago; Dr. Charles B. Puestow, Chicago; Dr. Ralph A. Reis, Chicago; Dr. Louis M. Rousselot, New York City; Dr. Harold A. Sofield, Oak Park, Ill.; Dr. Howard S. Van Ordstrand, Cleveland; and Dr. William L. White, Pittsburgh.

Dr. Maurice J. Ryan, president of the society, will open the first general assembly with an address. The Edward Holman Skinner Memorial Lecture, "Auto-Immune Hematologic Disease," will be given

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

by Dr. Dameshek. Breakfast seminars, round-table luncheons, symposiums, forums, and technical exhibits are planned.

MARYLAND

General Practice Meeting in Annapolis.—The 11th annual assembly of the Maryland Academy of General Practice will be held at Carvel Hall in Annapolis, Oct. 10-11. The program includes the following papers and speakers:

How to Avoid Professional Liability Claims, Mr. William J. McAuliffe Jr., Chicago.
The Conquest of Toxemia of Pregnancy, Dr. Frank A. Finnerty Jr., Washington, D. C.
Gout in Arthritis, Dr. John H. Talbott, Buffalo, N. Y.
The Use of Hypnosis in General Practice, Dr. Jacob H. Conn, Baltimore.
Freedom from Fear, Dr. Lester L. Coleman, New York City.
The Place of Genetics in General Medicine, Dr. Barton Childs, Baltimore.
New Tests to Aid in the Diagnosis and Management of Disease, Dr. Parker R. Beamer, Indianapolis.
Is the Family Unit Obsolete?, George Devereux, Ph.D., New York City.

The speaker at the annual banquet will be Dr. Fount Richardson, Fayetteville, Ark., president, American Academy of General Practice. The meeting will conclude with a clinical demonstration at the Anne Arundel General Hospital.

MICHIGAN

Dr. Wiley Named Secretary.—On June 24, Dr. Duncan B. Wiley, Utica, was elected as secretary of the Michigan State Medical Society to serve the expired term of the late Dr. L. Fernald Foster. Dr. Arthur E. Schiller, of Detroit, is the new chairman of the society council.

Begin New Headquarters Building.—The Michigan State Medical Society plans to have the expanded facilities of its new modern office building available for use by June, 1960. Situated at Highway M-78 and Abbott Road in East Lansing, the headquarters will have a parking area to accommodate 50 cars. The building has a central lobby two stories high which serves as the hub of the building, with no office more than 40 feet distant. On the first floor are located the offices of the president, editor, business manager, and bookkeeper, and an extra office for future growth. In the west wing are located the stenographers' room and an all-purpose room. The lower level contains workshops and storage rooms for radio transcripts, pamphlets, and the motion picture films from the PR library, and other equipment. The second floor will house the directors' room and a smaller committee room, opposite which the executive director and his assistant will be installed. The public relations library contains research data, periodicals, surveys, visual material for TV or speech presentations, news clippings, and reference works. A part-time librarian will be on hand. Other offices include a public relations council and staff and the secretary of the Medical Care Insurance Committees. A new telephone system is being installed which will have additional lines and will be operated by a modern keyboard console.

NEW JERSEY

Register Radiation Sources.—The New Jersey State Department of Health will begin in late October to register sources of radiation in New Jersey, according to Dr. Roscoe P. Kandle, state commissioner of health and a member of the New Jersey Commission on Radiation Protection. Registration of sources of radiation is required by Chapter 116, Public Laws of 1958. The first step will be the registration of radiation producing machines such as x-ray machines and high voltage rectifiers. This will be followed, later, by registration of radiation-producing materials, such as isotopes. The department will begin by sending a card to members of groups such as physicians, dentists, veterinarians, industrialists, and hospitals, who are known to use radiation-producing machines. Those who return the card indicating they have such machines will be sent the registration document to complete. Chapter 116 is the Radiation Protection Act. It called for creation of the Commission on Radiation Protection in the New Jersey State Department of Health. This nonsalaried Commission was set up and has been working since October, 1958, "to develop reasonable and practical measures to protect the public against injurious radiation."

NEW YORK

Postgraduate Week.—The New York Academy of Medicine will hold its third annual Postgraduate Week (formerly the Graduate Fortnight) Oct. 5-9 under the title, "Research Contributions to Clinical Practice." The program will consist of daily evening lectures, a scientific exhibit, and panel meetings on the following subjects: physiology and therapy of the gastrectomized patient; long-term results of surgery for acquired cardiovascular disease; iatrogenically induced liver disease; fertility and infertility; and problems in hypersensitivity. Although registration is required for nonfellows of the academy, no fee will be charged. For information, write the New York Academy of Medicine, 2 E. 103 St., New York 29.

Personal.—The appointment of Dr. Joseph L. Camp as deputy assistant commissioner in the New York State Department of Mental Hygiene was announced by Dr. Paul H. Hoch, New York City, commissioner of mental hygiene. Dr. Camp, assistant director at Letchworth Village, Thiells, assumed his new post Aug. 13. His duties will include medical inspection functions particularly in the mid-Hudson area.—The appointment of Dr. Bernard T. Brown, Syracuse, as director of the State Out-Patient Chest Clinic in Onondaga County was announced. Dr. Brown has been on the staff of Onondaga Sanatorium since 1942. The sanatorium was transferred to Onondaga County Aug. 27.—Dr. Robert E. Plunkett, Albany, retired Sept. 1 as the New York State Health Department's assistant commissioner for tuberculosis control. Dr. Plunkett had been associated with the State Health Department since 1923 when he was appointed superintendent of clinics and dispensaries. He was assistant commissioner for tuberculosis control since 1947.

New York City

Annual Salmon Lectures.—Curt Paul Richter, Ph.D., professor of psychobiology, Johns Hopkins Medical School, and director of the Psychobiological Laboratory at the Phipps Psychiatric Clinic, Baltimore, will give the 37th series of Thomas William Salmon Lectures at the New York Academy of Medicine on Wednesday afternoon and evening, Dec. 2. His subject will be "Biological Clocks in Medicine and Psychiatry." The afternoon lecture, to be delivered at 4:30 o'clock will be "Periodic Phenomena in Biology" and the evening talk at 8:30 will be "Periodic Phenomena in Medicine and Psychiatry."

Home for Disabled and Aged.—Construction has begun on a model home, the "Functional Home for Easier Living," on the grounds of the Institute of Physical Medicine and Rehabilitation, New York University-Bellevue Medical Center, Dr. George E. Armstrong, director of the center, announced. The one-level house, designed for the physically disabled, heart patients, and the elderly, is being contributed by James Rosati and Sons, builders from St. Petersburg, Fla., and will consist of two bedrooms, living room, dining area, kitchen, bathroom, and carport. All features of interior design are based upon the recommendations of the staff of the Institute of Physical Medicine and Rehabilitation. The kitchen has been planned in cooperation with the Home Bureau of the General Electric Company, which for the past 10 years has been working in research on problems of disabled homemakers in cooperation with the institute's activities of daily living, homemaking, and self help device services. Recommendations for the original model home have been incorporated into a brochure, "A Functional Home for Easier Living." The plan outlined in the brochure and carried out in the house has been developed as the result of 10 years of research with the following goals in mind: (1) to make it possible for a physically handicapped person to have independence in a wheelchair or with the use of a cane or crutches; (2) to make it easier to care for a dependent member of the family in a wheelchair; (3) to allow elderly persons or those with cardiac involvement and other heart problems to function with a minimum of energy. Copies of the brochure may be obtained from the Institute of Physical Medicine and Rehabilitation, 500 E. 34th St., New York 16. Adjacent to the institute, the "Functional Home for Easier Living" will be used as a model for visitors and for the training of disabled homemakers who are patients at the institute.

WISCONSIN

Midwest Rabies Station.—The Communicable Disease Center of the United State Public Health Service has established a Midwest Rabies Investigations Station at Poynette. An official opening for the station was held, with an open house Sept. 23 and a scientific meeting with discussions of the current status of research problems and wild life rabies, Sept. 24. For information, write the Communicable Disease Center, Bureau of State Services, 50 Seventh St., N. E., Atlanta 23, Ga.

Dr. Kempinsky Comes to Milwaukee.—Dr. Warren H. Kempinsky, an assistant professor of neurology at Washington University Medical School, St. Louis, has joined the Marquette University School of Medicine faculty and the medical staff of the Milwaukee County Hospital. Dr. Kempinsky will be a full-time neurologist at the Milwaukee County Hospital and the medical school. He will be in charge of the medical neurology services at the hospital, including the electroencephalography laboratory and will collaborate in further development of neuroradiology. Dr. Kempinsky has been appointed an associate professor of neurology at the School of Medicine.

GENERAL

Centennial of Anatomy Publication.—The American centennial edition of "Gray's Anatomy of the Human Body" was published during the week of Aug. 17. The first edition of Gray was published in this country by Lea & Febiger Publishers in June, 1859. This 27th edition is edited by Dr. Charles Mayo Goss, Louisiana State University School of Medicine, New Orleans, who has edited the two previous editions.

Recreation Congress In Chicago.—The 41st National Recreational Congress will be Sept. 28-Oct. 2 in Chicago with headquarters at the Morrison Hotel, under the theme, "Recreation in an Expanding Leisure." The keynote speech at the opening session will be given by Secretary of Health, Education, and Welfare Arthur S. Flemming. Mr. Homer C. Wadsworth, chairman, President's Citizens Advisory Committee on the Fitness of American Youth will speak at the third general session, presenting "The Role of Recreation in an Affluent Society." A symposium, "Is Recreation Doing Its Job?" is planned the morning of Oct. 2. Workshops, exhibits, and films sessions are arranged. Mr. Joseph Prendergast, executive director of the association, is chairman of the congress policy committee.

Annual Meeting of Anesthesiologists.—The American Society of Anesthesiologists will hold its annual meeting Oct. 4-9, at the Americana Hotel, Bal Harbour, Miami Beach, Fla., with the Florida Society of Anesthesiologists as hosts. Three panel discussions are planned: Medical Aspects of Space Flight; Tradition and Science in Premedication; Rescusitation: Pneumatic, Electronic and Expired Air. Scientific papers will be presented on work completed and work in progress. A program of 17 motion pictures is planned for Oct. 8 and 9. The 10th annual refresher course will be held Oct. 4-6. Scientific and technical exhibits are planned, and a ladies' program is arranged. On the evening of Oct. 6 a luau is planned.

Joint Annual Meeting in Vermont.—The 10th annual joint meeting of the New Hampshire Medical Society and the Vermont State Medical Society will be held Oct. 1-4 at the Equinox House, Manchester-in-the-Mountains, Vermont. The council meeting will be held the evening of Oct. 1, and the House of Delegates will meet the morning of Oct. 2. The theme and speakers for general sessions are as follows:

Oct. 2—Theme: Peptic Ulceration
  Speakers: Dr. Frank E. Harrigan Jr., Manchester; Dr. William R. Waddell, Boston; Dr. Franz J. Ingelfinger, Boston.
Oct. 3—Theme: Cancer
  Speakers: Dr. Roy Korson, Burlington; Dr. John H. Powers, Cooperstown, N. Y.; Dr. David A. Karnofsky, New York.
Oct. 4—Theme: Thyroid Gland
  Speakers: Dr. John B. Stanbury, Boston; Dr. Robert J. Vanderlinde, Hanover.

Sessions October 3 and 4 will be held on "Infections" (with Dr. Robert J. Anderson, Atlanta, Ga., and Dr. Colin C. Stewart, Hanover, as speakers) and "Steroids" (with Dr. David H. Streeten, Ann Arbor, Mich., as speaker). A clinical pathological conference will be moderated by Dr. Robert W. Coon, Burlington, the afternoon of Oct. 2. Prof. Dwight Salmon, of Amherst College, will be the speaker at the Friday night banquet, Oct. 2, speaking on "Latin America." A golf tournament is planned for the afternoon of Oct. 1. For information, write the Vermont State Medical Society, 128 Merchants Row, Rutland, Vt.

Life Expectancy Predictions.—Future gains in the life expectancy of the American people (close to 70 years) are expected to be more modest than those of the last two generations, statisticians of the Metropolitan Life Insurance Company report. By the year 2000, the expectation of life at birth in the U. S. is expected to be just over 74 years. This anticipated gain of less than 5 years contrasts with the 20 years added to the average lifetime between 1900 and 1957, the last year for which complete figures are available. The 1957 figure, 69.3 years, was 0.3 years below the all-time high registered in 1954 and 1956 but was above that for any year prior to 1954. Gains in longevity during recent decades have been greatest at the younger ages, the statisticians state. Since 1900 about 11.5 years have been added to the expectation of life at age 5, contrasted with an increase of 9 years at age 21 and of 5 years at age 40. At age 65, the average remaining lifetime has been extended by only about 2 years. In 1957 the expectation of life at age 65 was 12.7 years for white males and 15.4 for white females; at age 70, the figures were 10.1 and 12.1 years, respectively.

Clinical Scientists Meeting.—The annual meeting of the Association of Clinical Scientists will be held Oct. 10 at the Sheraton Hotel, Washington, D. C., to be preceded by a seminar, "Lipids and Steroids in Clinical Medicine," Oct. 9 and 10 at the Washington Hospital Center. Seminar discussions will cover the following:

- Lipids
  - Total Fats
  - Neutral Fats
  - Total Fatty Acids
  - Unesterified Fatty Acids
  - Cholesterol (free and esters)
  - Phospholipids
  - Lipoproteins
- Steroids
  - 17-Ketosteroids
  - Corticosteroids
  - Aldosterone
  - Estrogens
  - Progesterone

The annual banquet will be Oct. 10. The annual Sunderman Award to "the clinical scientist of the year," will be conferred on Dr. Earl B. Wert, pathologist of the Mobile Infirmary, at Mobile, Alabama. Dr. Wert will deliver an address, "The Training of Medical Technologists." For information, write Robert P. MacFate, Ph.D., 323 Northwood Road, Riverside, Ill., Secretary-Treasurer.

Grants for Pediatric Research.—The awards committee for the Mead Johnson Program for Pediatric Research of the American Academy of Pediatrics announced the availability for the coming year of funds to provide financial aid to young pediatric workers. These funds have been provided each year since 1958 by Mead Johnson & Company under rules established by the academy's awards committee. The maximum amount for any one grant in any year is $3,500. Grant applicants should be young pediatricians who are not more than 10 years beyond the completion of their residency.

These grants are specifically intended to encourage the young, unestablished, research-minded, academic pediatrician. Deadline for receipt of grant applications for July, 1960, will be Jan. 15, 1960. Interested persons should write to American Academy of Pediatrics, 1801 Hinman Ave., Evanston, Ill.

Safety Congress in Chicago.—The 47th National Safety Congress and Exposition will be held in Chicago Oct. 19-23 with headquarters at the Conrad Hilton Hotel. Papers will be presented on subjects concerning accident prevention fundamentals, radiation hazards, material handling, boat safety, air pollution, and other aspects of safety from the viewpoint of industry, the farm, the home, labor, transportation, the school, traffic, youth, and religious activities. At the banquet Oct. 20, 6:30 p.m., Mr. E. J. Thomas, chairman, The Goodyear Tire & Rubber Company, Akron, Ohio, will present an address. The theme for the meeting will be "Safety in the 60's." Safety films will be shown Oct. 21. The American Society of Safety Engineers will meet Oct. 20, and the 14th Annual Federal Safety Conference, sponsored by the Federal Safety Council, will be held Oct. 19-21. Exhibits are planned. For information, write the National Safety Council, 425 N. Michigan Ave., Chicago 11.

Meeting on Pediatrics.—The American Academy of Pediatrics will meet Oct. 5-8 at the Palmer House, Chicago, under the presidency of Dr. James C. Overall, Nashville, Tenn. Seminars, two-day instruction courses of limited enrollment, will be presented Oct. 3 and 4. Round-table discussions, half-day courses of limited enrollment, will run concurrently with the general sessions the afternoon of Oct. 5. The Borden Award Presentation, "The Search for Knowledge of the Child and the Significance of His Growth and Development," will be presented by Dr. Harold C. Stuart, Boston. The general discussions will include the following symposiums and chairmen:

Tranquilizers, Dr. James G. Hughes, Memphis.
Physiology of Respiration and Respiratory Problems, Dr. Charles D. Cook, Boston.
A Report on the Conference on the Role of the Pediatrician in the Prevention of Juvenile Delinquency, Dr. Preston A. McLendon, Washington, D. C.
The Acute Head Injury, Dr. Charles E. Koop, Philadelphia.
Metabolism of Fats, Dr. Laurance W. Kinsell, Oakland, Calif.
Respiratory Distress Syndrome, Dr. William A. Silverman, New York City.

Clinical conferences are planned for Oct. 8 at various hospitals. Section meetings are scheduled. Scientific and industrial exhibits, a program of entertainment, and a program of ladies' activities are arranged. The banquet ($7.50) will be held Oct. 7, 8 p. m. For information write the Executive Office of the Academy, 1801 Hinman Ave., Evanston, Ill.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

Fellowships for Sight Research.—The National Council to Combat Blindness, Inc., announced that upon the recommendation of its scientific advisory committee, the closing date for receipt of completed applications for "Fight for Sight" full-time research fellowships, grants-in-aid, and summer student fellowships has been designated as Jan. 1, 1960. This change of date was found necessary to facilitate the processing of the increased number of applications being filed with the organization for review by the committee. It will make possible notification in early spring to those applicants for full-time research fellowships where it has been established that this is essential. In such instances, the commencement date for the fellowship may be in advance of Aug. 1, but not prior to May 1. Appropriate forms may be obtained by addressing Secretary, National Council to Combat Blindness, Inc., 41 W. 57th St., New York 19. The National Council to Combat Blindness, Inc., was founded in 1946 with the primary purpose of financing research in ophthalmology and related sciences. The objective of its program is the "ultimate reduction of blinding eye diseases and ocular disorders, through increased basic and clinical research in this field of scientific investigation."

Fellowships for Tuberculosis Study.—The American Trudeau Society, the medical section of the National Tuberculosis Association, provides two types of fellowships to promote the training within this country of clinicians, medical teachers, and investigators in tuberculosis and respiratory diseases: (1) National Tuberculosis Association Fellowships—candidates holding the degrees of M.D., Ph.D., or Sc.D., are eligible for awards making possible continuation of graduate study in the field of respiratory diseases in an approved hospital or medical center. Such studies may be oriented toward either teaching or research. (2) Predoctoral Fellowships—offered to graduate students who hold a bachelor degree and are working on a research project for an advanced degree other than an M.D. Each applicant must have been accepted by the head of the department under whom he expects to work. Awards are determined by individual circumstances and are paid directly to the fellow on a quarterly basis. Fellowships are granted for one year and may begin on any date at the convenience of the applicant. Not more than two renewals will be considered. Fellowship applications must be received by Dec. 1. Edward Livingston Trudeau Fellowships at a higher level of training and award are offered to specially qualified candidates with an M.D. degree who have been assured of a continued teaching or research appointment upon completion of training. Trudeau fellowships are awarded for one year but may be renewed up to a total period of four years. Information concerning fellowships may be obtained from The Director of Medical Education, American Trudeau Society, 1790 Broadway, New York 19.

Armed Forces Institute Seeks Old Instruments.—The Armed Forces Institute of Pathology, Washington, D. C., is seeking military medical material to expand the famous collections of historical items in its Medical Museum which is one of the four major departments of the institute, a national institution jointly sponsored by the Army, the Navy, and the Air Force. The Museum has one of the finest collections of microscopes in the world, displayed to show the evolution of the microscope from its origin through the most recent developments in electron microscopy. Few microscopes have been added to this collection in recent years, and efforts are now being made to fill the gaps, particularly the years from 1920 to the present. The institute will celebrate its hundredth anniversary during and concurrently with the Civil War Centennial. Museum personnel are now planning the exhibits for this occasion. Through the long history of the institute a great number of historical instruments have been assembled, but among this material is very little of Confederate Army origin. Such items particularly are being sought. Although budgetary limitations preclude the purchase of such items, it is believed that there are a great number of instruments or other items which the owners might wish to place in the Museum where they will be carefully preserved for future generations. Any such donations would be greatly appreciated and due credit given. Persons having items they may wish to contribute are requested to write The Director, Armed Forces Institute of Pathology, Washington 25, D. C., relative to their acceptability and shipping instructions.

Smoking Among High School Students.—The American Cancer Society announced results of a new project in Portland, Ore., and surrounding area to study the smoking habits of 21,980 high school students. The study showed that about one-fourth of the boys and more than one-eighth of the girls smoke regularly every week, and most of them smoke every day. The findings are results of a study conducted by a group of researchers headed by Dr. Daniel Horn, director of program evaluation. The one-year study was started in May, 1958, and included students in 11 Portland public schools, 5 Catholic parochial schools, and 5 suburban public high schools in Multnomah and Clackamas counties. Involved were 11,060 boys and 10,920 girls. Results of the study showed:

(1) The percentage of smokers is highest among children of families in which both parents smoke cigarettes; lowest in families in which neither parent has been a smoker, and intermediate in families in which only one parent smokes cigarettes.
(2) The smoking behavior of boys tends to conform more closely to that of the father, while smoking behavior of girls follows more closely that of the mother.
(3) The percentage of smokers among children from families in which one or both parents continue to smoke is significantly higher than the percentage in which one or both parents gave up cigarette smoking.
(4) Each successive school grade has a higher percentage of smokers.
(5) The percentage of smokers is higher among students in Catholic parochial schools than among students in the city public schools. It is lowest among students in the suburban public high schools.
(6) The percentage of smokers among boys who do not participate in athletics is substantially higher than those who do and have a coach. The percentage of smokers is higher among students who do not participate in any school activities.

Personal interviews of a nation-wide sample of 4,000 high school students are also being conducted by an independent youth survey organization as a follow-up of the Portland study. The society board of directors authorized the project "as a means of finding the most effective way of presenting the facts about smoking to teenagers."

Surgeons Meet in Atlantic City.—The 1959 clinical congress of the American College of Surgeons will be held in Atlantic City, N. J., Sept. 28-Oct. 2. More than 1,500 physicians will take part in the program as authors of research papers, lecturers, discussion participants, and teachers. A panel on hospital infections moderated by Dr. Carl W. Walter, Boston, will officially open the meeting, Monday morning, Sept. 28. The 257 research-in-progress reports will be made during the week-long Forum on Fundamental Surgical Problems, under the chairmanship of Dr. Harris B. Shumacker Jr., Indianapolis. Nine postgraduate courses will be given. Principal speaker at the opening session will be Mr. Dean Rusk, president, the Rockefeller Foundation, with Dr. Newell W. Philpott, Montreal, president of the American College of Surgeons, presiding. The future of the college will be discussed in the presidential address Oct. 2 by the incoming president, Dr. Owen H. Wangensteen, Minneapolis. Dr. David P. Cuthbertson, Aberdeen, Scotland, will be guest speaker in an annual lectureship endowed by Baxter Laboratories, of Morton Grove, Ill. "Abdominal Injuries" is the title of the Trauma Oration, to be given by Dr. Rettig A. Griswold, Louisville. Color television of live operations performed at Bellevue Hospital in New York will continue throughout the week. Motion-picture demonstrations of surgical procedures and techniques are planned. Other sessions are a symposium on cancer, under the chairmanship of Dr. Danely P. Slaughter, Chicago; a symposium on graduate training in surgery, led by Dr. Robert M. Zollinger, Columbus, Ohio; and a display of more than 200 scientific and industrial exhibits.

LATIN AMERICA

Slide Seminar in Peru.—From Aug. 3 to 6 the Peruvian Society of Pathological Anatomy held its second slide seminar. The subject was "Tumors of Bones." It was conducted by Dr. David C. Dahline, from The Mayo Clinic, who gave a discussion of the 25 cases. It was attended by 120 pathologists, 24 from other Latin-American countries. The International Academy of Pathology gave support to this meeting in preparing 120 sets of slides. Parallel to the program of the seminar Prof. Isaac Costero, from Mexico, gave a short course on collagen diseases, and a scientific exhibit was prepared by members of the Peruvian Society of Pathological Anatomy. It is the aim of the society to extend to a wider scope among Latin-American pathologists, for attendance at this seminar each year. For information, write the Secretary, Committee of Seminars, Peruvian Society of Pathological Anatomy, Universidad Nacional Mayor de San Marcos de Lima, Facultad de Medicina, Lima, Peru.

FOREIGN

Beirut School Expands Research Program.—The American University of Beirut will strengthen the work of its Medical School in 1960 with the partial support of a grant of $24,000 from the Rockefeller Foundation. To give medical research the status it has in Western colleges as an important complement to teaching, the university is expanding this side of its activities. The size of the medical faculty will be increased, allowing each member greater opportunity for research, and a new building equipped with modern laboratory facilities will be constructed. For 30 years the medical school has pioneered the teaching of medical science in the

Middle East. Throughout its development, the medical school has been supported largely by American philanthropy. The Rockefeller Foundation has contributed some $3,000,000 toward instruction in medical sciences, nursing, and premedical subjects since 1924.

CORRECTION

Hemoglobinuria.—In the article "Hemoglobinuria After Massive Intraperitoneal Hemorrhage" (Aug. 15, pages 1912-1915) at the end of the first paragraph under the subhead Comment (page 1914) the last sentence should read "Intraperitoneal transfusions of citrated blood have been used in infants with satisfactory results.[4]"

EXAMINATIONS AND LICENSURE

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Written.* Various locations, July 8. Final date for filing application is January 8. *Oral.* Miami Beach, April 25-30. Applications already on file. Sec., Dr. Forrest E. Leffingwell, 217 Farmington Ave., Hartford 5, Conn.

American Board of Dermatology: *Written.* Several Cities, Oct. 5. *Oral.* Oklahoma City, Jan. 15-18, 1960. The final date for filing all applications was July 1, 1959. Sec., Dr. Beatrice M. Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *1959 Schedule—Written,* Oct. 19. Final date for filing application was May 1. *Oral.* For candidates on the East Coast, Nov. 6-7, 9-10. Final date for filing application was March 1. *Oral.* Philadelphia, March 11-12. Final date for filing application is January 15. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. New Haven, Nov. 14-16. Sec., Dr. Donald D. Matson, 300 Longwood Ave., Boston, Mass.

American Board of Obstetrics and Gynecology: *Part I, Written.* Chicago, January 16. *Part II, Oral.* Chicago, April 11-16. Final date for filing application was August 1. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Oral.* St. Louis, Oct. 6-10. *Written.* January 1960 in various cities. Applications for the 1960 written examination must be filed before July 1. *Oral.* 1960, San Francisco, May; Chicago, October. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago. Jan. 19-21, 1960. The deadline for the receipt of application was Aug. 15. Sec., Dr. Sam W. Banks, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-9. Final date for filing application was April 1. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: New Orleans, Nov. 12-14. Final date for filing application is October 1. Sec., Dr. Edward B. Smith, Indiana University Medical Center, 1100 W. Michigan St., Indianapolis 7.

American Board of Pathology: *Examination in Forensic Pathology.* New Orleans, Nov. 13. Final date for filing application is October 1. Sec., Dr. Edward B. Smith, Indiana University Medical Center, 1100 W. Michigan St., Indianapolis 7.

American Board of Pediatrics: *Oral.* Chicago, Oct. 9-11. *Written.* January 1960. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation: *Oral and Written.* New York, June 17-18. Sec., Dr. Earl C. Elkins, Mayo Clinic, Rochester, Minn.

American Board of Plastic Surgery: *Oral and Written.* Miami, Fla., Oct. 15-17. Final date for submitting case reports was July 1. *Oral and Written.* Milwaukee, May 1960. Final date for filing application is January 1. Corresponding Secretary, Mrs. Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8, Mo.

American Board of Psychiatry and Neurology: Chicago, Oct. 19-20; New York, Dec. 14-15; San Francisco, Mar. 14-15, 1960. Training credit for full time psychiatric and/or neurologic assignment in unapproved military programs or services between the dates of Jan. 1, 1950 and Jan. 1, 1954 was terminated on Jan. 1, 1959. Sec., Dr. David A. Boyd, 102-110 Second Ave. S. W., Rochester, Minn.

American Board of Radiology: *Examination.* Washington, Dec. 6-9. Deadline for filing application was July 1. Candidates examined in Diagnostic Roentgenology may expect to be examined in Physics. Obligatory examination in Nuclear Medicine has been postponed until after June 30, 1962 for those candidates being examined in Radiology or Therapeutic Radiology. Until that time the examination in Nuclear Medicine will be optional for those who wish to be examined in Radiology or Therapeutic Radiology. *Examination.* Cincinnati, Spring 1960. Deadline for filing applications is Jan. 1. A special examination in Nuclear Medicine (for those diplomates in Radiology or Therapeutic Radiology) will be offered provided there are sufficient applications. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Written* examinations (Part I) will be held on December 2, 1959 at various centers to be announced later. Closing date for filing applications was August 1. Those completing training requirements after September 30 cannot be considered for the Part I examination in December of the same year. *Oral examinations (Part II):* Baltimore, Oct. 19-20; Cincinnati, Nov. 9-10; Boston, Dec. 14-15; Winston-Salem, No. Car., Jan. 18-19; New York, N. Y., Feb. 15-16; New Orleans, Mar. 14-15; Kansas City, Kans., May 16-17, and Los Angeles, May 19-20. Sec., Dr. John B. Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

American Board of Urology: *Written.* Approximately 25 cities throughout the country, December 4, 1959. *Oral-Clinical* and *Examination in Pathology.* Chicago, February 1960. Final date for filing application was Sept. 1, 1959. Sec., Dr. William Niles Wishard, 30 Westwood Rd., Minneapolis 26, Minn.

DEATHS

Aeilts, Eerko Samuel Ⓜ Sibley, Iowa; Rush Medical College, Chicago, 1915; died in Sioux City June 25, aged 70.

Albano, Joseph, Newark, N. J.; Regia Universita di Napoli Facolta di Medicina e Chirurgia, Italy, 1902; associated with the Columbus Hospital; died in the Monmouth Memorial Hospital in Long Branch July 15, aged 82.

Alderdyce, William W., Toledo, Ohio; Toledo Medical College, 1900; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; past-president of the Toledo Academy of Medicine, of which he was trustee, secretary, and for many years treasurer; associated with the Flower Hospital; died July 3, aged 87.

Allen, Benjamin Gill, Henderson, N. C.; Columbia University College of Physicians and Surgeons, New York City, 1904; veteran of World War I; died in the Maria Parham Hospital July 5, aged 82.

Anderson, Axel Walfried Ⓜ Lakewood, Mich.; Northwestern University Medical School, Chicago, 1905; at one time practiced in Chicago; associated with the Mercy Hospital and the Hackley Hospital in Muskegon, where he died July 2, aged 82.

Bachmann, George William Jr. Ⓜ Honolulu, Hawaii; born in Rochester, N. Y.; Aug. 29, 1914; University of Southern California School of Medicine, Los Angeles, 1941; veteran of World War II and was awarded the Presidential Unit citation and Combat Medical Officers Badge; certified by the National Board of Medical Examiners; specialist certified by the American Board of Anesthesiology; member of the American Society of Anesthesiologists; associated with the Kauikeolani Children's Hospital and the Kapiolani Maternity and Gynecological Hospital; died in St. Francis Hospital July 3, aged 44.

Bennett, Max Ⓜ Attleboro, Mass.; Tufts College Medical School, Boston, 1922; on the staff of the Sturdy Memorial Hospital; past-president of the Attleboro Doctors Club; died July 5, aged 60.

Butler, Patrick Francis Ⓜ Boston; Harvard Medical School, Boston, 1903; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society, of which he was past-president; past-president of the New England Roentgen Ray Society; for many years on the faculty of his alma mater; in 1957 was presented an honorary doctor of science degree from Holy Cross College in Worcester; served on the staff of the Boston City Hospital, where he died June 29, aged 83.

Cantwell, Thomas Olin Ⓜ Harvey, Ill.; Rush Medical College, Chicago, 1935; member of the American Academy of General Practice; died in the Presbyterian–St. Luke's Hospital, Chicago, July 9, aged 60.

Cohen, George Louis Ⓜ Washington, Ill.; St. Louis University School of Medicine, 1928; member of the American Academy of General Practice; veteran of World War II; on the staffs of the Methodist and St. Francis hospitals, and the Proctor Community Hospital in Peoria, where he died July 8, aged 56.

Crews, Charles Hubert, Tampa, Fla.; Barnes Medical College, St. Louis, 1908; formerly practiced in Hammond, Ind.; died July 1, aged 78.

Cumming, Robert Ⓜ McGregor, Texas; L. R. C. P., Edinburgh, L. R. C. S., Edinburgh, and L. R. F. P. S., Glasgow, 1929; certified by the National Board of Medical Examiners; member of the American Academy of General Practice; health officer of McGregor; veteran of World Wars I and II; served on the staffs of the Veterans Administration Hospital and the Hillcrest Hospital in Waco; immediate past-president of the McGregor Rotary Club; died July 6, aged 59.

Dewey, Jay Reed Ⓜ Schaller, Iowa; University of Illinois College of Medicine, Chicago, 1923; past-president of the Sac County Medical Society; past-president of the Iowa division of the American Cancer Society; served on the county board of education and the board of education of Schaller; veteran of World War I; associated with the Loring Hospital in Sac City and the Buena Vista County Hospital in Storm Lake, where he died July 3, aged 68.

Dorsey, Frank Donald, Portland, Maine; Hahnemann Medical College and Hospital of Philadelphia, 1921; member of the staffs of the Maine Medical Center and the Mercy Hospital, where he died July 4, aged 64.

Draper, George Ⓜ New York City; born in New York City May 21, 1880; Columbia University College of Physicians and Surgeons, New York City, 1906; specialist certified by the American Board of Internal Medicine; member of the Association of

---

Ⓜ Indicates Member of the American Medical Association.

American Physicians and the American Society for Clinical Investigation; formerly associate professor of clinical medicine at his alma mater; veteran of World War I; served on the staffs of Nassau Hospital in Mineola, N. Y., and the Presbyterian Hospital; in 1947 appointed medical director of the Winifred Masterson Burke Relief Foundation at White Plains, N. Y., retiring in 1950; author of "Acute Poliomyelitis," "Disease and the Man," and "Infantile Paralysis"; died July 11, aged 79.

Duszynski, Leonard Ⓜ Buffalo; University of Buffalo School of Medicine, 1913; died June 12, aged 69.

Ferlita, Americo James Ⓜ Tampa, Fla.; Loyola University School of Medicine, Chicago, 1934; member of the American Academy of General Practice; associated with the Centro Asturiano Hospital and the Tampa General Hospital; died July 2, aged 51.

Fromkin, Charles, Bridgeton, N. J.; Jefferson Medical College of Philadelphia, 1917; died in the Bridgeton Hospital July 6, aged 63.

Garland, James Monroe, Indianapolis; University of Louisville (Ky.) Medical Department, 1910; died July 5, aged 80.

Gillett, Josephine Merle Danforth, North Madison, Ohio; Cleveland Medical College, Homeopathic, 1897; University of Wooster Medical Department, Cleveland, 1903; member of the board of trustees of the Woman's Hospital, Cleveland, where she died June 28, aged 85.

Gutheil, Emilian Arthur Ⓜ New York City; Medizinische Fakultät der Universität, Vienna, Austria, 1930; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; served as secretary of the Association for the Advancement of Psychotherapy; author of "The Handbook of Dream Analysis" and "Language of the Dream"; editor of "Patterns of Psychosexual Infantilism" and "Autobiography: the Life Story of a Pioneer Psychoanalyst"; died in the Mount Sinai Hospital July 7, aged 60.

Hackett, George Clifford Ⓜ Portville, N. Y.; Jefferson Medical College of Philadelphia, 1914; past-president of the Cattaraugus County Medical Society; veteran of World War I; associated with the Olean General Hospital and St. Francis Hospital in Olean, where he died June 22, aged 68.

Hammond, William Thomas, Easton, Md.; Hahnemann Medical College and Hospital of Philadelphia, 1909; specialist certified by the American Board of Radiology; member of the Radiological Society of North America; veteran of World War I; past-president of the Medical and Chirurgical Faculty of Maryland; associated with the Memorial Hospital; died July 10, aged 72.

Harrison, William Barnett Ⓜ Athens, Ga.; Georgetown University School of Medicine, Washington, D. C., 1905; served as assistant director of the division of maternal and child health of the Georgia State Board of Health and regional medical director for both the northeastern and northwestern regions; at one time commissioner of health in Hall County; died July 8, aged 76.

Hessert, Edmund Charles Ⓜ Camden, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1926; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the International College of Surgeons and the American College of Surgeons; professor emeritus of gynecology at his alma mater; associated with Camden County General Hospital in Blackwood and West Jersey Hospital; died in Absecon July 5, aged 57.

Hill, Eugene Scott Ⓜ New York City; University of Nebraska College of Medicine, Omaha, 1932; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; veteran of World War II; formerly practiced in Canton, Ohio, where he was associated with the Mercy Hospital and on the courtesy staff of the Aultman Hospital; director of professional education, American Cancer Society; died in the Regent Hospital in New York City July 3, aged 52.

Hill, Robert Leroy Ⓜ Winfield, Ala.; Memphis (Tenn.) Hospital Medical College, 1905; served as president of the Marion County Medical Association; formerly member of the state legislature; medical director of the Winfield Hospital; president of the Citizens Bank of Winfield; died in the Winfield Hospital July 1, aged 77.

Hollard, Alfred Edward Ⓜ Belding, Mich.; Chicago College of Medicine and Surgery, 1914; for many years health officer; died in the Butterworth Hospital, Grand Rapids, July 1, aged 76.

Hooper, Kendall Ⓜ Flint, Mich.; University of Michigan Medical School, Ann Arbor, 1938; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; veteran of World War II; secretary treasurer of the Flint Academy of Surgery; associated with the McLaren General Hospital, where he died July 1, aged 45.

Horenstein, Perry Samuel Ⓜ Bellport, N. Y.; Harvard Medical School, Boston, 1930; certified by the National Board of Medical Examiners; member of the American Academy of General Practice; past-president of the Sulfolk County Medical Society; physician for the Bellport school system; associated with the Brookhaven Memorial Hospital in Patchogue and the Mather Memorial Hospital in Port Jefferson; died July 13, aged 54.

Ives, Robert Franklin Ⓜ Houston, Texas; Columbia University College of Physicians and Surgeons, New York City, 1895; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; formerly practiced in Brooklyn, where he was associated with the Methodist and Bay Ridge hospitals; died June 30, aged 89.

Jennings, Perry Wells Ⓜ Canton, Mo.; Washington University School of Medicine, St. Louis, 1908; member of the American Academy of General Practice; twice vice-president of the Missouri State Medical Association; for many years secretary of the Lewis-Clark-Scotland Counties Medical Society; for many years on the board of trustees of Culver-Stockton College, where he was physician; charter member and first president of the Canton Kiwanis Club; director of the board that organized the Canton State Bank; physician for the Chicago, Burlington and Quincy Railway System; died July 7, aged 75.

Jillson, Walter Arthur, Palo Alto, Calif.; Boston University School of Medicine, 1905; specialist certified by the American Board of Psychiatry and Neurology, Inc.; fellow of the American Psychiatric Association; veteran of World War I; retired from the Veterans Administration Feb. 28, 1951; at one time superintendent of the Central State Hospital in Lakeland, Ky.; died in the Veterans Administration Hospital, San Francisco, July 8, aged 78.

Jones, Pius Henry, York, Pa.; Baltimore University School of Medicine, 1902; also a graduate in pharmacy; formerly county coroner; died June 30, aged 86.

Kaarboe, Olav Ⓜ Oakland, Calif.; College of Physicians and Surgeons of San Francisco, 1917; veteran of World War II; for many years associated with the St. Francis Hospital; died July 4, aged 72.

Kackley, Ellis Dyson Ⓜ Beaumont, Texas; Starling-Ohio Medical College, Columbus, 1911; veteran of World War I; died in the Hotel Dieu Hospital July 1, aged 76.

Keller, William Lordan Ⓜ Colonel, U. S. Army, retired, Washington, D. C.; born in Connecticut March 24, 1874; Medical College of Virginia, Richmond, 1899; commissioned in the medical corps of the U. S. Army in 1902 while in Manila during the Philippine Insurrection; served at numerous posts in the United States; retired Oct. 31, 1935; as a result of his services in World War I was awarded the Distinguished Service Medal, decorated by the British government and made an officer in the French Legion of Honor; in 1953 was paid a high tribute when an annual lecture series at Walter Reed Army Medical Center was named in his honor; known officially as the William L. Keller Memorial Lecture, the program is presented each year at the Army Surgeon General's meeting; in 1936 a bronze bust of him was installed in the entrance lobby of the main building of the Walter Reed General Hospital, where he served as chief of surgery and lifetime consultant; member of the founders group of the American Board of Surgery; member of the American Surgical Association; fellow of the American College of Surgeons; in 1931 received the honorary degree of doctor of science from his alma mater; died in the Walter Reed Army Hospital July 10, aged 85.

Kelly, Marcus Gerald Ⓜ San Diego, Calif.; St. Louis University School of Medicine, 1932; died in the Sharp Memorial Hospital July 3, aged 52.

Kidd, Ruth Williams Ⓜ Haverford, Pa.; Long Island College of Medicine, Brooklyn, 1941; certified by the National Board of Medical Examiners; served on the staff of the Hospital of St. Barnabas and for Women and Children in Newark, N. J.; died July 2, aged 65.

Larrison, Glen David, Morocco, Ind.; Hering Medical College, Chicago, 1913; veteran of World War I; associated with the Jasper County Hospital in Rensselaer; died near Eagle River, Wis., June 29, aged 70.

Littig, Lawrence Victor Ⓜ Shore Hills, Wis.; State University of Iowa College of Medicine, Iowa City, 1921; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and the American College of Radiology; first president of the Wisconsin Radiology Society; chairman of the Section on Hospitals of the American Medical Association, 1916-1917; veteran of World War I; for many years associated with the Madison General Hospital; served on the staffs of the St. Mary's Ringling Hospital in Baraboo, Fort Atkinson (Wis.) Memorial Hospital, and the Reedsburg (Wis.) Municipal Hospital; died July 6, aged 62.

Livingood, Louis Jacob Ⓜ Wyomissing, Pa.; Jefferson Medical College of Philadelphia, 1917; for many years president of the school board of Womelsdorf; past-president of the Berks County Medical Society; veteran of World War I; associated with the Reading (Pa.) Hospital, where he died July 3, aged 66.

Lovelace, Virgil Andrew, Cape Girardeau, Mo.; Hospital College of Medicine, Louisville, 1904; died in St. Francis Hospital June 11, aged 78.

Maxfield, George Henry Ⓜ Bridgewater, Mass.; Harvard Medical School, Boston, 1903; veteran of World War I; served on the staffs of the Soldiers'

Home in Massachusetts, Chelsea, Boston State Hospital, and the Bridgewater State Hospital; died July 2, aged 83.

Neumann, Conrad A. Ⓜ Winona, Minn.; Northwestern University Medical School, Chicago, 1909; fellow of the American College of Surgeons; associated with the Winona General Hospital; died July 6, aged 77.

Pawling, Philip Sheridan Ⓜ Evanston, Wyo.; St. Louis College of Physicians and Surgeons, 1917; associated with the Wyoming State Hospital, where he died May 27, aged 72.

Pennock, Elmer Lorne Ⓜ Harrison, N. Y.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1912; served as a captain in the medical corps of the Canadian Army during World War I; member of the staffs of St. Agnes Hospital in White Plains, St. Vincent's Hospital in Harrison, and the United Hospital in Port Chester; director of the medical department, Harrison Public School System; for 38 years school physician, and town health officer for 15 years; died in the United Hospital, Port Chester, June 29, aged 75.

Percy, Irving Everett, Chicago; Loyola University School of Medicine, Chicago, 1924; died July 8, aged 60.

Perkins, Charles Norman Ⓜ Burlington, Vt.; University of Vermont College of Medicine, Burlington, 1905; veteran of World War I; alderman for many years; South Burlington health officer; associated with the DeGoesbriand Memorial Hospital and Mary Fletcher Hospital, where he died June 15, aged 79.

Pitt, Cullen Ⓜ Richmond, Va.; University College of Medicine, Richmond, 1905; past-vice-president of the American Student Health Association; for many years physician at the University of Richmond, where he was physician to its athletic association, and where a portrait was presented by the alumni on his retirement; from 1925 until 1956 served as assistant medical director and then as medical director of Atlantic Life Insurance Company; assistant medical director of Mutual Life Insurance Company of Virginia from 1946 to 1956, when he was elected medical director; died July 10, aged 79.

Posey, Gifford O. Ⓜ Tucumcari, N. M.; Southwestern Homeopathic Medical College and Hospital, Louisville, Ky., 1903; formerly practiced in Cimarron, where he served two terms as mayor; died in the Tucumcari General Hospital July 1, aged 81.

Quint, Sumner Joseph, Burbank, Calif.; University of Southern California College of Medicine, Los Angeles, 1899; for many years practiced in Los Angeles; died July 3, aged 87.

Rambo, David T. Ⓜ Ottumwa, Iowa; College of Physicians and Surgeons, Keokuk, 1897; formerly practiced in Chillicothe; associated with Ottumwa and St. Joseph hospitals; died July 3, aged 85.

Raymond, R. O., Phoenix, Ariz.; Washington University School of Medicine, St. Louis, 1899; practiced in Flagstaff; died in St. Joseph's Hospital July 6, aged 82.

Reed, Woodie N. Ⓜ Amory, Miss.; born in Fulton Feb. 2, 1877; Memphis (Tenn.) Hospital Medical College, 1901; past-president of the East Mississippi Medical Society; member of the board of trustees of Amory city schools for two terms; a charter member and past-president of the Amory Kiwanis Club; formerly practiced in Fulton, where he was health officer of Itawamba County; local surgeon for the Frisco Railroad from 1914 to 1928 and also served as division surgeon for the railroad from 1918 until 1952; chief of staff and formerly superintendent of Gilmore Sanitarium; died in the Baptist Memorial Hospital, Memphis, Tenn., June 30, aged 82.

Rosenberg, Louis, Brooklyn; Regia Università degli Studi di Roma. Facoltà di Medicina e Chirurgia, Italy, 1932; associated with the Williamsburg General Hospital; died May 26, aged 56.

Rudulph, Charles Murray Ⓜ Birmingham, Ala.; Medical College of Alabama, Mobile, 1900; veteran of World War I; associated with the South Highlands Infirmary and St. Vincent's Hospital, where he died July 2, aged 79.

Segall, Samuel, Baltimore; Thüringische Landesuniversität Medizinische Fakultät, Jena, Thuringia, Germany, 1930; interned at Mount Pleasant Sanatorium in Reisterstown, Md.; died in Washington, D. C., March 25, aged 55.

Senteff, Louis Henry Ⓜ St. Petersburg, Fla.; Medical College of Alabama, Mobile, 1904; veteran of World War I; member of the American Trudeau Society; served as medical superintendent of the Mount Logan Sanatorium in Chillicothe, Ohio; died in St. Anthony's Hospital July 2, aged 80.

Shultz, Harry M. Ⓜ Logansport, Ind.; Medical College of Indiana, Indianapolis, 1903; veteran of World War I; formerly county health officer; for many years on the medical staff of the Pennsylvania Railroad; served on the staff of St. Joseph Hospital and the Memorial Hospital, where he died June 28, aged 86.

Shumate, David Larkin Ⓜ Kansas City, Mo.; Barnes Medical College, St. Louis, 1896; associated with the Kansas City General Hospital, Research Hospital, and St. Joseph Hospital; died in St. Luke's Hospital July 8, aged 85.

Sidis, Sarah Mandelbaum, Miami Beach, Fla.; Boston University School of Medicine, 1897; formerly practiced in Portsmouth, N. H., where she was medical director of the Sidis Institute; died July 9, aged 85.

Silbert, Samuel Ⓜ New York City; Columbia University College of Physicians and Surgeons, New York City, 1917; veteran of World War I; associated with the Montefiore Hospital, where he was attending surgeon; consulting surgeon in peripheral vascular disease at Mount Sinai Hospital, where he died July 10, aged 65.

Sirken, Charles Ⓜ Jersey City, N. J.; University and Bellevue Hospital Medical College, New York City, 1917; veteran of World War I; secretary of the medical advisory board from 1939 to 1945 and president of the medical board from 1945 to 1947 at the Christ Hospital, where he died July 4, aged 65.

Sophian, Lawrence Henry Ⓜ Medical Director, U. S. Public Health Service, retired, New York City; born in New York City June 26, 1903; Harvard Medical School, Boston, 1925; joined the teaching staff of his alma mater as an instructor in pathology; left this post in 1929 to assume the position of associate professor of pathology at the New York Post-Graduate Medical School; in 1930 appointed [illegible] at Roosevelt Hospital, where he [illegible]tering the U. S. Public Health Service in 1939; served at the U. S. Marine Hospital, Staten Island, N. Y., as director of laboratories and research; later was promoted to medical director of the U. S. Public Health Service and retired in 1952 with the rank of captain; specialist certified by the American Board of Pathology; member of the American Association of Pathologists and Bacteriologists and the College of American Pathologists; at one time member of the medical department of Lederle Laboratories; medical director and vice-president of William Douglas McAdams, Inc., a pharmaceutical advertising agency; joint author of "The Sulfapyrimidines"; died in the Roosevelt Hospital July 8, aged 56.

Sphar, Robert Argyle Ⓜ Brownsville, Pa.; Medico-Chirurgical College of Philadelphia, 1910; associated with the Brownsville General Hospital; died in the Presbyterian Hospital, Pittsburgh, July 2, aged 78.

Staats, James Clinton Ⓜ California, Ky.; Eclectic Medical College, Cincinnati, 1917; formerly practiced in Cincinnati, where he was associated with the Deaconess Hospital; died in St. Luke Hospital of Campbell County, Fort Thomas, July 1, aged 67.

Stewart, Ernest Richard Vernon Ⓜ Cincinnati; Eclectic Medical College, Cincinnati, 1924; associated with Our Lady of Mercy Hospital in Mariemont, Ohio, Speers Memorial Hospital in Dayton, Ky., St. Elizabeth Hospital in Covington, Ky., and Bethesda Hospital in Cincinnati; died near Marathon July 5, aged 70.

Stone, Abraham Ⓜ New York City; born in Russia Oct. 31, 1890; University and Bellevue Hospital Medical College, New York City, 1912; served as associate clinical professor of preventive medicine at his alma mater and as a faculty member of the New School for Social Research; from 1923 to 1927 instructor in urology at the New York Post-Graduate Medical School; veteran of World War I; fellow of the American Society for the Study of Sterility and the New York Academy of Medicine; since 1941 director of the Margaret Sanger Research Center; founder and president of the American Association of Marriage Counselors and vice-president of the Planned Parenthood Federation of America; in 1947, at the request of the State Department, was appointed by the National Research Council as delegate to the first World Conference on Family and Population at Paris; in 1951 the World Health Organization of the United Nations named him a special consultant on family planning in India and Ceylon; in 1947 received the Albert and Mary Lasker award for his work in planned parenthood; consultant in urology at the Sydenham Hospital; joint author of "A Marriage Manual," "Planned Parenthood," and "Premarital Consultation"; editor of the *Journal of Human Fertility* from 1936 to 1949; died in New York Hospital July 3, aged 68.

Tolstoouhov, Alexander Vladimir, New York City; Russian University of Warsaw Faculty of Medicine, 1920; died in St. Luke's Hospital July 9, aged 70.

Truscott, Joseph Robert, Binford, N. D.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1901; president of the school board; for services during World Wars I and II received presidential citations; died in Northwood June 27, aged 88.

Venus, Charles Henry, York, Pa.; Baltimore Medical College, 1902; died July 5, aged 87.

Wanlass, Stanley Adrian Ⓜ Harrison, N. Y.; George Washington University School of Medicine, Washington, D. C., 1923; veteran of World War I; honorary police surgeon and served as school doctor at Harrison Avenue School; associated with the United Hospital in Port Chester; vice-president of the Rye (N. Y.) National Bank; died in Rye July 12, aged 66.

Weidman, David Henry, Buffalo; University of Buffalo School of Medicine, 1932; associated with the Deaconess Hospital; died July 1, aged 51.

FOREIGN LETTERS

AUSTRIA

New Orally Given Diuretic Agent.—At the meeting of the Society of Physicians in Vienna on May 29, H. Schnack and F. Wewalka compared the results obtained with hydrochlorothiazide, an orally administered diuretic agent, with those obtained when chlorothiazide was used. For the former a small dose (25 to 150 mg.) was effective and a slight blocking of carbonic anhydrase, manifested by a decreased potassium excretion, was noted. The effect continued for 24 to 48 hours with adequate doses. Although removal of edematous fluid in cardiac patients was prompt, no diuresis was produced in patients with cirrhosis of the liver. This difficulty was overcome by doubling the dose or by combination with agents which released carbonic anhydrase. Not even mild psychic changes were ever observed in any of a series of 31 patients with cirrhosis of the liver. The drug was well tolerated and it could be given in small maintenance doses over a prolonged period.

Perphenazine for Psychoses.—At the same meeting, E. Frühmann and H. Gross reported that they had treated 150 psychotic patients with perphenazine. The effect of the drug is similar to that of chlorpromazine. Relief of anxiety and decreased aggression, motor unrest, and impairment of thinking was observed. In addition to the rapid production of sedation, the disappearance of hallucinations and the prompt dissolution of the manic mood were remarkable. As a result of this treatment a much earlier institution of psychotherapy and occupational therapy was possible. In patients with melancholia and endogenous depression the anxiety and excitability were improved but because the depression was greatly increased the drug is contraindicated in such patients. Epilepsy presents an absolute contraindication. The dosage must be determined individually, since the unpleasant side-effects depend chiefly on the patient's constitution and general condition.

Treatment usually started with the intramuscular administration of 5 mg. of the drug three times daily for three days followed by the oral administration of 8 mg. four times a day. In some patients doses up to 80 mg. might be given parenterally. Because of the undesirable side-effects, the speaker recommended simultaneous administration of an antiparkinsonian agent starting with the institution of treatment. Threatening side-effects may be combated with thenalidine and caffeine. Life-threatening conditions of this type were observed in only one patient. The effect of perphenazine ranged between that of chlorpromazine and that of reserpine, but perphenazine seems to be superior to these two drugs because of its effect on the schizophrenic process.

BRAZIL

Surgical Infections.—Dr. J. G. Ramos (*Revista Brasileira de Cirurgia,* May, 1959) studied a series of 110 "clean" surgical operations. There was no indication that the use of antibiotics under such circumstances prevented complications or reduced the number of postoperative days in hospital. On the contrary, their prophylactic use engendered a false sense of security and gave rise to an increase of postoperative complications through relaxation of the rigid rules of asepsis. In the same issue Drs. Fernando Paulino and A. C. Neto compared a series of 100 patients subjected to various operations without the prophylactic use of antibiotics with other groups of such patients to whom antibiotics were given routinely. They concluded that antibiotics should be given only when definitely indicated.

Wounds of the Hands.—Dr. L. B. Abreu of São Paulo (*Revista do Hospital das clínicas,* vol. 14, May-June, 1959) pointed out the importance of early treatment of wounds of the hand. Primary repair of nerves and tendons is the ideal treatment, but this should not be attempted unless (1) the wound is fresh and clean, (2) the surgeon and assistant are thoroughly familiar with the anatomy of the hand and have mastered atraumatic technique, (3) a fully equipped operating room is available, (4) the patient is prepared to undergo a long operation under general anesthesia, and (5) he can be closely watched in the first two postoperative days. If these conditions cannot be observed, it is safer to cleanse the wound, perform a débridement, and suture the skin. Secondary repair three to four weeks later will still give these patients excellent results.

Chloroquine for Mycoses.—Dr. N. Belliboni reported to a meeting of the Associação Paulista de Medicina that he had treated a patient who had sporotrichosis with chloroquine and obtained com-

---

plete regression of the nodular and lymphangitic lesions in a little more than 20 days. He treated other patients who had sporotrichosis with this drug. Although an in vitro test had shown that the drug did not inhibit the growth of Sporotrichum and Paracoccidioides, these other patients also showed marked improvement. The speaker then used the same drug to treat blastomycosis, chromomycosis, and actinomycosis, but in these patients so treated for 30 to 60 days, the results were inconclusive. He had the impression that a patient with lupoid blastomycosis improved slightly, but when the treatment was stopped the initial condition returned. In this patient oral administration of the drug caused a severe gastritis so the drug was given parenterally. The author believed that the good results of the use of chloroquine in sporotrichosis, in spite of the inactivity observed in vitro, could be due to the transformation of the drug in the liver, where it might be split into chemical compounds of an unknown nature, which could be responsible for the curative action.

Teratomatous Ovarian Chorioepithelioma.—Dr. Paulo Torres, of the University of Juiz de Fora (*Rev. ginec. e obst.* 53:385, 1959) reported a case of teratomatous chorioepithelioma of the ovaries in a girl 7 years of age. Chorioepithelioma is a rare tumor and its teratomatous variety is independent of any previous pregnancy. The history of the patient was that she had had an accelerated physical development in the three months prior to admission, mainly in the external genitalia, with normal menstrual periods, asthenia, fever, and a painful swelling of the abdomen. She had the aspect of an adolescent girl, with pubic and axillary hairs and breasts well developed, large labia majora, and cornification of the vaginal epithelium. The swelling in the low abdomen was as large as a pregnant uterus in the fifth month. The more important laboratory findings were positive Galli Mainini test results, increased excretion of urinary gonadotropins and estrogens as well as pregnanediol and 17-ketosteroids. Vaginal cytology showed hyperestrogenic changes.

The hypothesis of pregnancy having been ruled out, a tentative diagnosis of chorioepithelioma was made, and the patient was operated on 19 days after admission. A huge tumor mass was found involving the ovaries and tubes in continuity with the external surface of the uterus. Other small tumors were found on the parietal peritoneum and intestinal loops. These tumors were polypoid, soft, and had a dark red color similar to that of placental tissue. Microscopic examination confirmed the presence of a chorioepithelioma by showing atypical placental trophoblasts (mainly Langhans' cells), areas of necrosis, hemorrhage, hyperemia, vascular proliferation, and a few embryonal structures. There was no invasion of the uterine deep layers or endometrial glandular hyperplasia, decidual transformation of the chorionic cells, nor muscular hypertrophy. This case was of interest because of the rarity of the condition and the positive histological diagnosis.

DENMARK

Posture in Boys.—Asmussen and Heebøll-Nielsen (*Acta orthop. scandinav.* 28:174-189, 1959) studied 201 schoolboys, aged 7 to 16 years, to determine whether there was a correlation between the form and function of the back and to see how these factors change during the school years. It has been postulated that school life with its compulsory sedentary work caused deterioration of the backs of children, even though gymnastics and other forms of physical education were thought to compensate for it. The subjects all took part in compulsory physical exercises three or four hours a week. It was found that lumbar lordosis increased but kyphosis and pelvic inclination decreased with increasing body weight. Flexibility of the spine seemed to increase with height in forward flexion and to remain constant in backward flexion. A tendency to a positive correlation between lumbar lordosis, kyphosis, pelvic inclination, muscular strength, and flexibility of the spine was also found. The authors concluded that a strong and flexible back most often also had more pronounced curves and vice versa. The normal range of degrees of curvatures was large (plus or minus 25% of the mean). Any attempt to "straighten" a curved but otherwise normal back by exercises or training consequently should be discouraged and most probably would fail by itself.

Side-effects from Isoniazid and PAS.—Olsen and Tørning (*Acta tuberc. scandinav.* 37:89-103, 1959) studied a series of 52 ambulatory tuberculous patients, most of whom had continued treatment with isoniazid and PAS after leaving the hospital. The total duration of chemotherapy was at least one year, except in one patient. Twenty-eight patients had psychological side-effects which in 18 were ascribed to isoniazid, and in 10 probably to other contributory causes. The symptoms were fatigue, impairment of concentration and memory, depression, and unbalanced state of mind. They usually became obvious within the first months of ambulatory treatment even in those patients who started with a fairly long treatment in the hospital. In most patients the symptoms continued for the duration of ambulatory treatment but disappeared within one or two months after discontinuance of treatment. The frequency of manifest psychological side-effects presumably was much higher in this series of private patients than the average, but the observations reported here justify a stronger interest in these symptoms than had hitherto been shown. The author made a plea for caution in the large-scale use of isoniazid as prophylactic therapy in healthy persons.

Ulnar Perineuritis.—Progressive arthrogenous paralysis of the ulnar nerve arises by mechanical action on the nerve where it passes the elbow joint. This mechanical action on the nerve may be due to deformity of the joint after a fracture and the paralysis then appears after a latent period which may be several years. The paralysis may also arise in connection with an arthrotically deformed elbow joint, habitually increased cubitus valgus of the elbow joint, and chronic external trauma. In order to eliminate the detrimental action on the nerve, operation is indicated in most patients.

Erik Jensen (*Acta psychiat. et neurol. scandinav.* 34:205-221, 1959) operated on a series of 40 such patients. In 39 an anterior transposition of the ulnar nerve was performed and in one a bursa was removed from the ulnar groove. At a follow-up examination of 39 of the patients 1¾ to 9½ years after the operation, it was found that in one patient the condition was slightly aggravated, in 2 it was unchanged, in 6 it was slightly improved, in 18 it was much improved, and in 12 it was cured. The author concluded that the slighter the paralysis and the shorter its duration the greater was the chance of full restitution by operation. Patients with incipient paralysis of the ulnar nerve thus ought to be subjected to operation as soon as possible.

Chlorpropamide.—Chlorpropamide is a hypoglycemic compound that differs chemically from tolbutamide only insofar as Cl is substituted for CH_3 in the para-position. V. Esmann and co-workers (*Acta med. scandinav.* 164:73-79, 1959) studied the clinical effect of chlorpropamide in 20 diabetic patients whose ages ranged from 41 to 85 years. Diabetes was newly diagnosed in five patients. The duration of the disease was less than 5 years in six patients, between 6 and 10 years in four patients, and more than 11 years in five patients. Six patients had diabetic retinopathy. Chlorpropamide was found to be effective and well tolerated by 14 of the patients when given in a dosage of 0.5 Gm. per day. One patient even did well on a dosage of 0.25 Gm. daily. When more than 0.5 Gm. was given daily mild hypoglycemic reactions were occasionally observed.

The treatment was stopped in two patients who developed fever and a rash. In one of them the treatment was resumed later without reappearance of fever or skin manifestations. None of the patients complained of nausea. Three patients complained of alcohol sensitivity with a flushing reaction similar to that following the use of disulfiram. The study of kidney function, liver function, and the hematological status revealed no changes during the four-week period. The elimination of chlorpropamide from the body was slow. The biological half-life in the serum is about two days. Chlorpropamide caused an increase in intravenous dextrose tolerance and a slight decrease in inorganic phosphate and potassium levels.

Fibrinolysin in Thrombotic Diseases.—Jørgen Røjel (*Acta med. scandinav.* 164:81-93, 1959) stated that until now fibrinolysin activity has been determinable only by methods too complicated for use in clinical routine. He devised a simple method based on the observation by Hagedorn that serum possesses certain protamine-splitting properties. Brunfeldt and Poulsen found this protamine-splitting property to be due to fibrinolysin as the effect became accelerated by addition of streptokinase and inhibited by addition of ionized zinc. Addition of lysine ethyl ester would inhibit the protamine-insulin-splitting property of serum because of its specific inhibiting effect on fibrinolysin.

In the present study the author determined the streptokinase activity and the spontaneous fibrinolysin activity in serums from patients with thrombotic disturbances and from normal subjects, the fibrolysin activity being expressed by the half-life, i. e., the time required by a serum to reduce by 50% the turbidity of the solution. In serums from normal subjects the activated half-life was found to be 5.31 minutes and the spontaneous half-life was found to be 2.12 minutes. In serums from patients with thrombotic disturbances the activated half-life was 12.18 minutes and the spontaneous half-life was 2.39 minutes. Comparison of these two groups showed a much lower fibrinolysin activity in serums from patients with thrombotic disturbances than in those from normal subjects. Moreover the investigation demonstrated the remarkable fluctuation of the fibrinolysin activity throughout the course of the thrombotic disturbance and usually this activity would be found to be low coincidentally with the onset of an aggravation in the clinical condition.

With a view to precluding the possibility of anticoagulant treatment by heparin from influencing the fibrinolysin activity, one patient with a physiological disease was treated with anticoagulant drugs. Throughout the treatment his fibrinolysin activity remained normal. In patients in whom infarction could not be diagnosed on the basis of clinical and electrocardiographic findings the author suggested that the fibrinolysin analysis might be of use. In one patient with a mesenteric thrombosis a reduced fibrinolysin activity was recognized and hence the diagnosis could be made before operation. In another patient the fibrinolysin activity remained low for nine days after the leg had been amputated. This feature might be explained on the principle that the fibrinolysin combined with such fibrin as formed in the wound secretion. Gradually as the secretion from the wound subsided the fibrinolysin values became normal.

Bowel Function in the Puerperium.—Bach and Ingerslev (*Acta obst. et gynec. scandinav.* 38:88-92, 1959) investigated the bowel function in 411 puerperal women. Of the patients who were allowed out of bed on the first postpartum day 40% had a spontaneous bowel movement daily after the reestablishment of bowel function as compared with 30% of those not allowed out of bed until the fourth postpartum day. Spontaneous bowel movement occurred in 60% of the patients before the sixth postpartum day. The patients allowed out of bed on the first postpartum day had a spontaneous bowel movement earlier than those allowed out of bed on the fourth postpartum day. The authors concluded that routine treatment with cathartics during the puerperium was not justified. If help is needed the authors recommended the use of suppositories and if these do not produce the desired effect magnesium sulfate should be given.

Quantitative Determination of Gonadotropins.—S. G. Johnsen (*Acta endocrinol.* 31:209-227, 1959) determined quantitatively the amount of hypophysial gonadotropins in 24-hour urine specimens in 295 normal subjects (118 men aged 25 to 96 years, 38 women aged 18 to 49, 64 women aged 51 to 87, and 75 children aged 9 to 15). In the men the excretion of gonadotropins rose continuously with age starting in the early 30's. At the age of 70 the mean value was about twice as high (58 units) as in young men (30 units). The level of values in men was far from the level of values reached by postmenopausal women. The mean value of 20 units in the younger and regularly menstruating women was lower than in the young men and was independent of age so long as regular menstruation was present. As regarded the influence of the menstrual cycle on the excretion of gonadotropins, 12 women had a sudden rise in gonadotropin excretion in the middle of the cycle. Before and after this rise the level was about the same. In the older and postmenopausal women the climacteric caused a tenfold rise in the values from that of the childbearing age. The mean value in the group 50 to 64 years of age was 210 units.

In the children it was found that for the boys the gonadotropin excretion was somewhat lower than in men, with an average of 14 units, and in girls the excretion was on the average almost the same as in women. The author concluded that the normal values for the excretion of hypophysial gonadotropins in urine varied with age and sex. Commenting on the so-called male climacteric he stated that the testicular steroid production showed a slow steady decrease starting in the 30's but never completely ceased within the normal lifespan. A sudden gonadal change comparable to the menopause in women does not occur, as a state of castration is not reached, and it is therefore meaningless to speak of a male climacteric.

Chlorothiazide as a Diuretic.—Tage Hilden and coworkers (*Nord. med.* 61:717-719 [May] 1959) gave 57 patients who had edema chlorothiazide as a diuretic in 72 periods of treatment of 5 days' duration and in 24-hour doses of 1 or 2 Gm. The drug was an effective diuretic. An increase of the 24-hour dose from 1 to 2 Gm. caused only a slight increase in the diuretic effect. Generally chlorothiazide produced only minor alterations in the plasma levels of chloride, sodium, and bicarbonate ions. The most essential electrolytic change was a fall in the plasma potassium level. Pathologically low values appeared in six patients. No correlation was observed between the fall in the serum potassium level and a change in weight. A marked fall in the serum potassium level could be seen when the diuretic effect was only slight or failed to appear. Practically no immediate side-effects were seen. One patient developed an eruption of the skin. The kidney function estimated from the serum creatinine level remained uninfluenced except in one patient with thrombosis of a renal vein.

Renal Damage due to Acetophenetidin.—Larsen and Møller (*Acta med. scandinav.* 164:53-71, 1959) questioned 698 patients over 20 years of age admitted to the department of medicine of the County and Municipal Hospital of Vejle and found that 205 or 29.4% took acetophenetidin-containing drugs daily and 156 or 22.3% took them occasionally; 98 patients, or 14%, had taken the drug daily for six years or longer. Twice as many women as men took acetophenetidin daily and the women tended to take larger doses and to continue for longer periods than the men. The renal function was found to be reduced in 68 (33.2%) of the 205 patients who took the drug daily. This finding differed significantly from the findings of reduced renal function in 29 (8.6%) of 337 patients who did not take acetophenetidin and 17 (10.9%) of 156 patients who used it occasionally.

This incidence of reduced renal function was found to increase with the intensity of the dosage and the duration of administration. These findings were regarded as definite proof that acetophenetidin had an injurious effect on the kidneys. Of 21 patients whose total consumption of the drug was 7 kg. or more, 17 had reduced renal function, and these results uniformly indicated a renal lesion characterized by reduced ability to concentrate and reduced filtration. Hypertension, retinopathy, or edema were not encountered. Infections of the urinary tracts were frequent but did not occur until acetophenetidin had been used for many years and must be regarded as secondary. Because prolonged use of this drug in large doses indicates genuine drug addiction, preparations containing it should not be obtainable without a prescription.

FINLAND

Skin Arthroplasty.—K. O. Kettunen (*Acta orthop. scandinav.* 28:190-197, 1959) used skin graft arthroplasty in 122 operations on different joints. In connection with later arthrotomies performed on two such joints tissue samples were examined microscopically. These samples revealed cartilaginous metaplasia. These specimens showed no signs of intra-articular irritation. The epidermal cells had become destroyed and no epidermal cysts had formed. The necessary condition for the metaplastic process was articular weight-bearing. In one patient in whom the ulnar joint surface was not covered with a skin graft, the granulation tissue growing from the joint surface retained its vitality and underwent a metaplastic development into cartilage. It therefore seemed evident that, if the articular cartilage was removed from both articular surfaces, investing only one of the articular surfaces with interposition material was sufficient. Histochemical increase of acid mucopolysaccharides in the ground substance of connective tissue was noted. The new cartilage was of either fibrous or hyaline type. The author concluded that the human organism tolerates a full-thickness skin graft used as interposition material well. The epidermis of the skin graft becomes destroyed and no epithelial cysts form. In the connective tissue used as interposition material a metaplastic development into cartilage takes place when this tissue is subject to joint function.

Normal Distribution of Pulmonary Function Between the Lungs.—The mean ratio of the functions of the two lungs and the physiological variation are not only of theoretical interest but also of practical significance for evaluation of the results of bronchospirometry. V. Autio (*Ann. med. int. Fenniae* 48:9-13, 1959) studied the results of bronchospirometry in 22 healthy volunteers, 5 men and 17 women, their mean age being 24.8 years, none of whom had any history of pulmonary disease. Since for various reasons the ratio of the vital capacities of the lungs can be considered the most reliable measure of the differential function, the mean ratio of the functional capacities of the right and left lungs could be taken to be 53:47 ± 5%. Thus if the total vital capacity of a subject were 5,000 cc., the vital capacity of the right lung could vary between 2,400 and 2,900 cc. and still be normal.

Phenethyldiguanide for Diabetes.—M. Reinikainen (*Ann. med. int. Fenniae* 48:25-35, 1959) studied the effect of phenethyldiguanide (DBI) on 15 diabetics aged 26 to 79 years (average 60) who had used carbutamide or tolbutamide previously but whose blood sugar level had remained over 200 mg. per 100 ml. in spite of these drugs. Most of the patients also complained of fatigue and thirst. Of these patients eight had taken carbutamide or tolbutamide for a year or longer. DBI lowered the blood sugar level in nine patients. In three of these the drug caused nausea and vomiting and in one it caused diarrhea. In the youngest patients acidosis was present throughout the sulfonylurea treatment and did not disappear during DBI therapy, although doses of 200 mg. lowered the blood sugar level effectively. Vomiting necessitated discontinuation of the treatment. There were no side-effects in the remaining six patients in whom the blood sugar level fell in response to treatment with DBI. In four of these the urine also became free from sugar. The author concluded that the fact that DBI produced a pronounced fall in blood sugar level in 9 of 15 patients was significant especially since none of them had responded satisfactorily to sulfonylurea therapy.

Acute Bacterial Meningitis.—Most patients treated for acute bacterial meningitis are infants and young children. Only occasionally is the adult population affected. Kauhtio and Jansson (*Ann. med. int. Fenniae* 48:33-43, 1959) reported a series of 95 patients over 15 years of age who were treated for acute bacterial meningitis. In the years 1937 to 1946 Neisseria meningitis accounted for 60% of the cases but from 1947 to 1956 Streptococcus pneumoniae predominated, accounting for 63% of the cases. Meningococcic meningitis tended to affect adolescents and persons under 40 years of age whereas 67% of the patients with pneumococcic meningitis were over 40. The disappearance of meningococcic meningitis with only three verified cases observed since 1945 might be explained by the increasing use of various antibiotics in treating almost every febrile illness. The mortality was 9% during the early years. In patients with pneumococcic meningitis treated with penicillin the mortality was 13%. Intrathecal administration of antibiotics seemed unnecessary. Meningitis caused by bacteria other than the two mentioned was rare. There were only seven such patients in the 20-year observation period. Four of these recovered.

For the patients showing meningeal signs and symptoms and often presenting diagnostic and therapeutic problems, the authors recommended examination of a direct smear of the spinal fluid. When no bacteria are found but the cell count is in the hundreds antibiotics should not be given unless there are some other indications and the spinal puncture should be repeated the next day. In patients with serous meningitis the cells are predominantly, if not exclusively, lymphocytes, whereas in untreated bacterial meningitis the polymorphonuclear cells predominate, the sugar concentration usually decreases, and the general condition of the patient deteriorates. By this time there also will be some bacterial growth in the culture of the spinal fluid obtained by the first puncture. The authors concluded that an early bacteriological diagnosis was of great importance when selecting appropriate treatment. The administration of several antibiotics and sulfonamides simultaneously as a routine measure could not be recommended. In some patients purely supportive measures, if applied early, might be lifesaving.

Theophylline Sodium Glycinate.—Oral administration of theophylline and many of its derivatives which have a low solubility in water often causes gastrointestinal irritation. Therapeutic plasma levels cannot therefore always be attained. One of the new theophylline derivatives, theophylline sodium glycinate, readily soluble in water is now available. Seppälä and Kärkelä (*Ann. med. exper. et biol. Fenniae* 37:59-62, 1959) attempted to determine whether therapeutic plasma levels of theophylline could be attained by oral administration of theophylline sodium glycinate to 13 hospital patients in good condition and without any gastrointestinal disease. Every subject received a single dose of 0.9 Gm. of theophylline sodium glycinate (equivalent to 0.45 Gm. of theophylline). The therapeutic plasma level above 1 mg. per 100 ml. was reached in all 13 subjects usually after one or two hours. In eight subjects the theophylline plasma level after five hours was still above 1 mg. per 100 ml. The trial dose did not cause gastrointestinal irritation or other side-effects in any of the subjects. The authors, however, concluded that the therapeutic value of theophylline sodium glycinate depended on the frequency of side-effects in maintenance treatment.

Systemic Lupus Erythematosus.—T. Vartio (*Ann. med. exper. et biol. Fenniae* 37:86-88, 1959) used the simple precipitation test for systemic lupus erythematosus, introduced by Jones and Thompson, on 98 patients with various disorders. Of 10 patients with systemic lupus erythematosus the test was positive in 3. In one untreated patient the test was negative but after two weeks it became positive. In another patient treated for six months with cortisone, ACTH, and chloroquine, the test was negative, but after a month it became positive. The results obtained were similar to those previously obtained. The test cannot be considered specific for systemic lupus erythematosus.

Rheumatoid Arthritis.—Laine and Julkunen (*Ann. med. exper. et biol. Fenniae* 37:100-104, 1959) studied the bentonite flocculation test (BFT) in 100 adults (86 women and 14 men) with rheumatoid arthritis. The BFT was positive in 64% which was less than expected in view of previous investigations. There was no correlation between the BFT and the sedimentation rate. The duration of the disease did not seem to affect the incidence of the positive reaction.

Infrared Spectroscopy in Chemical Identification.—Infrared spectroscopy is the best and most rapid method for the identification of pure organic compounds when the spectrums of these compounds are available. Alha and Tamminem (*Ann. med. exper. et biol. Fenniae* 37:157-174, 1959) reported that since 1957 the Institute of Forensic Medicine of the University of Helsinki has been equipped with an infrared spectroscope with attached microscope. Thirty-one cases of suspected fatal poisoning were investigated in which the identification of the separated substances and the exclusion of suspected substances was made mainly by infrared spectroscopy. The materials investigated were specimens of body organs removed at autopsy and medicines that had been taken by the dead person. In the separation of volatile substances one of the techniques used was steam distillation after precipitation with acetone. Nonvolatile substances were separated with acetone and the crude product obtained was fractionated into four groups.

In the group of acid and neutral substances "water purification" was used and when necessary the separation of neutral substances and fractionation of acid substances into two groups was done. The further treatment of the fatty mass obtained by acetone treatment was performed in two cases in which carbromal and methion (Mesantoin) were separated. Further procedures of purification and separation were sublimation, ion exchange, and chromatography on silica gel. The latter allowed the separation of pentobarbital and carbromal and of pentobarbital and bromisovalum. With use of the infrared spectrums the following substances separated from cadaverous materials were identified: trichloroethylene, parathion, p-nitrophenol, DDT, Systox (an insecticide), acetophenetidin, bemegride, meprobamate, tertiary amyl isovalerate, methoin, bromisovalum, carbromal, sedormid, butabarbital, phenobarbital, pentobarbital, barbital, aminopyrine, chloroquine, quinine, quinidine, and morphine. Mixtures of meprobamate and acetophenetidin and of amobarbital and pentobarbital were detected in two spectrums. The authors concluded that the infrared identification of toxic substances called for a large collection of spectrums of toxic substances.

Effect of Camphor on Coagulation.—Kivalo (*Ann. med. exper. et biol. Fenniae* 37:227-237, 1959) investigated the mechanism of the hemostatic effect of camphorated oil in nine healthy subjects. When administered intramuscularly it was found to reduce the time of coagulation markedly. Camphor injection produced no positive change in the prothrombin index whereas a reduction in the thrombocyte count might occur. No effect on blood calcium was noted. The reduction of the time of coagulation was thought by the author to be caused by a breakdown of thrombocytes resulting in a higher content of thromboplastin-producing substances in the blood. These investigations supported the contention that the prompt use of camphorated oil for pulmonary hemorrhage was fully justified. On the other hand, its use should be avoided when there is a risk of thrombosis.

Trichomycin.—Vartiainen and Ryynänen (*Ann. chir. et gynaec. Fenniae* 48:100-105, 1959) treated a series of 50 patients who had vaginitis with trichomycin. In 46 patients there was a positive culture of Trichomonas vaginalis. In the remaining four, T. vaginalis were found in the catheterized urine. The control group consisted of 50 patients with vaginitis in whose cultures no T. vaginalis were found. In 78.3% of the patients in whom the culture was negative, no subjective or objective signs of colpitis worthy of mention appeared after treatment. In 15.2% of the patients the subjective symptoms had disappeared almost entirely and objectively only a few organisms were found but both the culture and the cytological smears showed the continued presence of T. vaginalis. In only three patients or 6.5% could no result be ascertained from treatment. The organisms were still abundant and the vaginal mucosa was clearly inflamed. The antibiotic caused no side-effects but trichomonal cystitis did not respond to this treatment.

Prematurity Studies.—Dr. C. E. Räihä (*Nordisk medicin,* May 28, 1959) studied a series of about 2,000 pregnant women. The volume of each mother's heart was measured at some time after the fourth month of pregnancy and on the first day after confinement. The figures thus obtained were correlated with the duration of pregnancy and the weight of the child at birth. The smaller the volume of the mother's heart, the greater was the risk of prematurity. When mothers had a heart volume of less than a certain figure obtained by x-ray examinations in two dimensions, it was found that the risk of prematurity could be greatly reduced by having the mother avoid heavy work and rest at intervals throughout the day. Since prematurity is a mirror of the standard of living of a given community, the risk of it may be 1 to 2% when the standard of living is high. In the various Scandinavian countries it is about 5%. The present study shows that in Finland it is possible to reduce this figure to 2.4%. It should be noted that among the 86,985 infants born in Finland in 1957, 1,514 were stillborn and 1,179 died within the first week of life, giving a perinatal mortality of 3.1%.

Rehabilitation After Brain Damage.—Dr. E. Hillbom (*Nordisk medicin,* July 16, 1959) estimated that Finland has about 4,700 persons who had incurred a cerebral injury. Of these 3,552 were available for statistical analysis. They were treated in (1) a hospital that treated them as inpatients or outpatients and provided facilities for a thorough examination and appropriate treatment, (2) a hostel that housed the totally disabled for whom room could not be found at home, and (3) an institution that provided much varied occupation for the partially disabled who could not quite hold their own in a competitive society.

A special study of 415 veterans showed that 17% had a 0 to 25%, 64% had a 30 to 65%, and 19% had a 70 to 100% disability. Epilepsy occurred in 41%. It was present in 14% of the veterans with slight injuries and in 74% of those whose injuries were severe. The epilepsy was practically cured in 10%, sometimes spontaneously. All of the patients with slight injuries were at work, and so were 97% of the patients with moderately severe injuries, but these were not always full-time jobs. Only 47% of the subjects with severe injuries were at work and in some instances the work was part-time. Of this material as a whole it could be claimed that 86% continued to be active members of the community, capable of earning a living with the aid of the pensions to which they were entitled, 74% had returned to their former occupations, and 13% had successfully undergone training for a new occupation.

Reduction of Respiratory Function by Disease.—Ville Autio (*Acta tuberc. scandinav.* 37:112-125, 1959) performed bronchospirometries on 132 patients with unilateral tuberculous lesions to determine the loss of function occasioned by parenchymal and pleural involvement of varying degree. He found that, whereas parenchymal lesions affected only a small loss of pulmonary function, pleural lesions were much more serious in this respect. By computing the relative contributions of the healthy and affected sides to the predicted vital capacity for the patients examined, it was established that the decrease in the vital capacity of the affected side was not accompanied by an increase in the vital capacity of the contralateral side. The contributions of the affected side to the total oxygen uptake, vital capacity, and ventilation were found to increase in this order. The differences, however, were not large and the distribution of vital capacity between the lungs was believed to reflect the differential function fairly well.

The greater relative ventilation, i. e., relative hyperventilation of the affected lung as compared with its relative oxygen uptake, was especially evident in patients with severe pleural complications. The author concluded that loss of function after resection depended decisively not only on the amount of parenchymal tissue removed but also on the subsequent reaction of the pleura. The seriousness of pleural complications was evidence of the importance of proper hemostasis, postoperative removal of any blood that might have entered the pleural cavity, and immediate expansion of the lung.

GERMANY

Rheumatic Syndrome.—Kraus and Koll (*Med. Klin.* 54:861, 1959) reported that treatment with a mixture of chloroquine diphosphate, aspirin, and prednisone (Elestol) for a maximum of nine months gave distinct improvement in two patients who had spondylarthrosis ankylopoietica (analgesia after two or three weeks and free mobility after five weeks in one patient and slow subjective improvement in the other) and in 22 of 27 patients with recent activation of chronic rheumatoid arthritis (excellent results in 7, good results in 11, and moderate subjective improvement, usually beginning after three to eight days, in 4 patients). Marked and persistent regression of inflammatory swelling and improvement of joint mobility usually occurred in the second week of treatment. Radiographic controls showed no distinct changes. In one nurse no reactivation occurred when work was resumed, although this had happened regularly before. The sedimentation rate declined by 50% in 7 of 10 patients. Improvement of the inflammatory constellation in the serum electrophoresis was demonstrated in 25% of the patients.

When careful trials were made to withdraw the preparation, symptoms recurred but responded well when the drug was used again. No effect was observed in osteoarthritis. As regards side-effects edema developed in three, allergic exanthema in one, and euphoria in isolated patients. About 25% noted gastric pressure in the initial phase of treatment. When distinct improvement had been achieved, the medication was gradually changed to a course of chloroquine alone for 6 to 12 months. Severe reactivations were observed after patients had deliberately discontinued taking the tablets.

Antistreptolysin Reaction in Tuberculosis.—Hudemann and Maas (*Tuberkuloseärzt* 13:192, 1959) made three determinations of the antistreptolysin titer (AST) at intervals of 14 days in 100 patients with tuberculosis (41 with progressive and 59 with regressive forms). Although no streptococcic or rheumatic diseases were clinically observable, elevated values and significant changes of AST were noted in 33% and 25% of the patients respectively. The reason for these changes was not determined. It was not possible to demonstrate an influence of specific chemotherapy on the behavior of the titer. It appears that the antistreptolysin titer in patients with pulmonary tuberculosis requires a critical approach. To suggest a rheumatic condition in tuberculous patients merely from an increased AST does not seem to be justifiable.

Iron Metabolism.—Heilmeyer and Keiderling (*Deutsche med. Wchnschr.* 84:724, 1959) made quantitative determinations of the absolute amount of iron used for hemoglobin synthesis and of the amount of iron not used for this purpose with the aid of radioactive iron in 7 healthy persons, 17 patients with infectious diseases, and 9 with malignant tumors. In those with infections and malignant tumors the incorporation of hemoglobin iron and the turnover of nonhemoglobin iron in erythrocytes were increased. The mean life span of erythrocytes is 60 days in infections, while in health it is about 100 days.

Vitamin C and Ovulation.—T. Nakajima of Kiel (*Zentralbl. Gynäk.* 81:337, 1959) stated that the vitamin C level may offer a further means of determining the time of ovulation. Basal temperature, determination of eosinophils in the peripheral blood, and determination of the pyknosis index from vaginal smears were referred to for comparison. Vitamin C levels were determined in the urine. In a healthy woman with regular menses the vitamin C level showed marked variations in the course of two cycles. The lowest levels were seen at the beginning of and shortly before menstruation. Another lowering of the ascorbic acid level was observed one day after the lowest basal temperature reading in both cycles. In five patients receiving gonadotropin for ovarian insufficiency lowering of the vitamin C level at the time of ovulation was also demonstrable. Uncharacteristic fluctuations were seen in two women who did not respond to gonadotropin. It was not considered feasible to determine the time of ovulation from the vitamin C level alone.

Responsiveness of Corticosteroids to Corticotropin.—J. R. Bierich and co-workers (*Acta endocrinol.* 31:40-48, 1959) reported that under maximum stimulation with long-acting corticotropin given intramuscularly the 17-hydroxycorticosteroids in 25 normal children rose within eight hours from 11.2 ± 2.8 mcg. per 100 ml. to 37.0 ± 6.0 mcg. per 100 ml. The same stimulation given to children receiving prednisone for longer periods resulted in significantly lower values. Longer duration of treatment was paralleled by progressively lower values. After continuous therapy for six months or more the mean basic values were 4.0 mcg. per 100 ml. and the mean final values 5.7 mcg. per 100 ml. After abrupt cessation of the therapy the tests did not become normal until four to seven days later, but the risk of adrenal insufficiency could be reduced by diminishing the doses gradually. Tests which were performed during long-term treatment with additional administration of corticotropin or during intermittent therapy, with prednisone given only four days in the week, showed results within normal limits.

Ten children with rheumatic fever were treated by long-term therapy with depot-ACTH. Daily doses of 30 to 70 I. U. of corticotropin per square meter of body surface led to progressively higher levels of 17-hydroxycorticosteroids, which after several weeks reached values between 70 and 120 mcg. per 100 ml. The basic levels, however, were also low in these patients. Obviously the adrenal cortex had not atrophied but hypertrophied. In contrast to this the corticotropic activity of the hypophysis seemed to be diminished in the same way as after therapy with corticosteroids.

Insulin-Zinc Suspension.—Eckler and Koch of Bremen (*München. med. Wchnschr.* 101:1219, 1959) treated 37 diabetic children daily with insulin-zinc suspension (IZS), most of them for several years. After being treated for several years with two injections of other insulin preparations 17 patients could be treated with only one injection of IZS a day. Twenty patients were treated from the beginning with only one injection of IZS a day. Follow-up examination revealed excellent results in 20 and satisfactory results in 12 patients. The results in five could not be judged, because the follow-up period was too short. In spite of the severity of the disease in most of the children no metabolic disturbances were noted.

Cesarean Section and Diabetes.—A series of 35 pregnancies complicated by diabetes was reviewed by H. J. Siegler (*Geburtsh. u. Frauenh.* 19:384, 1959). Cesarean section was preferred by the author to other methods of delivery in these patients because it greatly reduces perinatal mortality. Peridural anesthesia combined with a "lytic cocktail" consisting of 100 mg. of meperidine, 50 mg. of chlorpromazine, and 50 mg. of promethazine was preferred to inhalation anesthesia because it was not accompanied by a rise in blood sugar level and did not cause fetal asphyxia.

Intracranial Hypertension.—The blood and urine of 210 patients with cerebral tumors with no direct effect on the hypophysis and hypothalamus were examined by Herbert Brilmayer (*Acta endocrinol.* 31:130-136, 1959) who found that in acute intracranial hypertension, parallel with its intensity, leukocytosis, eosinopenia, lymphopenia, sodium and chloride retention, and an increase in the excretion of free corticoids and 17-ketogenic steroids occurred in the urine. In chronic intracranial hypertension no significant findings were observed beyond a slight leukocytosis. When after a chronic course the increase in intracranial pressure reached an excessive degree the findings of an increased steroid excretion and an increased potassium-sodium ratio obtained in acute intracranial hypertension were generally reversed. Thus, values were found which were significantly diminished far below the normal range. Consequently there was a relationship between the intensity and the course of intracranial hypertension on the one hand and the endocrine state on the other. These findings showed that an increased intracranial pressure which had not existed for more than six weeks led to activation of the adrenocortical system.

Cor Pulmonale.—Before starting treatment for chronic cor pulmonale, it is useful to distinguish between a more or less permanent stage of compensation and periodic decompensation due to infection. Management of this condition is still one of our most difficult problems, but knowledge of the associated disorders of function produced therapeutic possibilities that have greatly improved the prognosis. Treatment of the peripheral circulation is of great importance. Treatment in general consists of (1) antibiotics for the endobronchial infection resulting in bronchospasm, (2) relief of the bronchospasm, and (3) relief of hypoxemia. Patients with respiratory paralysis are the most difficult to treat. The author prescribes analeptics for these patients. This permits the simultaneous treatment of several patients in a general hospital without the use of a respirator.

HUNGARY

Private Practice Curtailed.—The Hungarian daily newspaper *Nepszabadsag* (March 28, 1959) announced that a recent government decree had made it impossible for a physician to devote his time exclusively to private practice. Only if the doctor has a full-time job in a state organization is he allowed to have some private patients. The Minister of Health was claimed to be the final authority to determine under what circumstances a physician could have a private practice.

JAPAN

BCG Vaccine.—Ebina and Saito (*Acta tuberc. scandinav.* 37:162-174, 1959) reported comparative studies on the prophylactic and protective value of BCG vaccine. A group of 3,211 BCG-vaccinated and 2,615 unvaccinated students, nurses, and inhabitants of two farm villages were observed for one to four years. The morbidity from tuberculosis per 1,000 persons was significantly lower in the vaccinated than in the unvaccinated. Among nurses observed for four years the morbidity was 20.2 per 1,000 for the 198 unvaccinated and 14.4 per 1,000 for the 208 vaccinated. Tuberculosis was observed four times as often in 1,990 unvaccinated persons ranging in age from 14 to 25 years who attended the outpatient clinic because of symptoms suggestive of tuberculosis as in 2,147 vaccinated persons attending the clinic. In the outpatients acute forms of tuberculosis such as miliary, pneumonic, and mixed type with cavity formation occurred more frequently in the unvaccinated while indurative types occurred more frequently in the vaccinated.

Concerning the extent of lesions, more patients with moderately advanced and far-advanced tuberculosis were seen in the former group and more patients with minimal tuberculosis in the vaccinated. Among a group of 90 vaccinated and 282 unvaccinated patients hospitalized because of the serious nature of their tuberculosis, the condition of 92.2% of the vaccinated and 77.7% of the controls improved. The condition of the remaining 7.8% of the vaccinated and 22.3% of the unvaccinated remained unchanged or became worse. The mortality from tuberculosis in all three groups studied was significantly higher in the unvaccinated than in the vaccinated. No significant differences were observed in the occurrence of tuberculosis and the type of disease in 252 persons who had received nonlyophilized BCG vaccine as compared with 378 who had received lyophilized vaccine.

KOREA

National Tuberculosis Association.—An armistice agreement in 1953 halted the military fighting in Korea, but the people of South Korea are still waging warfare on many other fronts. The ravages of war left a nation plagued by overcrowding, malnutrition, breakdowns in sanitation, and shortages of medical supplies. Among the most widespread of the war-spawned diseases is tuberculosis. Its incidence in South Korea is 4%, or 13 times the rate reported in the United States. Because of the need to support their families, many of those with open lesions cannot be isolated. A bright spot in this dismal picture is the effort of 300 volunteer workers who comprise the Korean National Tuberculosis Association. These dedicated persons, although struggling themselves to live in an insecure economy, have sacrificed their time and efforts without pay to battle tuberculosis.

Three treatment centers are now operating at Seoul, Taegu, and Kwangju. The clinics follow a procedure of mass roentgenography and centralized treatment which was established for the Republic of Korea by the United States Army Advisory Group. Each new patient is registered, given a medical examination, roentgenograms are taken, and if tuberculosis is found the patient may be treated at the center. Despite limited facilities and equipment, the doctors, nurses, and technicians are able to process 100 patients a day. As in the United States, the chief source of funds is the annual sale of Korean Christmas seals. Additional money from government subsidies, United States contributions, contributions from United States personnel stationed in Korea, and the sale of tuberculosis literature and subscriptions to the *Journal of Tuberculosis* aid in the work of the association.

The association is also conducting an active educational program in the form of lectures, demonstrations, and refresher courses for workers at government health centers. Magazines, films, posters, and pamphlets are supplied to schools and civic groups to combat public ignorance and misconceptions about tuberculosis. The association also sponsors vaccination for school children. This program, initiated in 1950 by a group of Scandinavian doctors, is being carried on by the association. Last year 80,000 children received BCG vaccination. The results of this program are paying off in a dropping incidence of tuberculosis for this age group. The association also furnishes grants-in-aid for tuberculosis research. Funds have been set aside for three additional free clinics to be established

NORWAY

Comparison of Analgesics.—Ivar Lund (*Nord. med.* 61:854-856 [June 4] 1959) compared the analgesic effect of dihydrocodeine with that of morphine, meperidine, and a placebo of saline solution in 218 patients with postoperative pain. Satisfactory relief of pain was obtained with 90% of 156 doses of morphine, with 87% of 160 doses of meperidine, with 77% of 188 doses of dihydrocodeine, and with 47% of 90 doses of saline solution. The author suggested that the analgesic effect of dihydrocodeine ideally should be compared with a dose of morphine that produced no more respiratory depression than did the optimal dose of dihydrocodeine (30 mg. per 70 kg. of body weight). This would possibly provide information as to whether or not relief of pain and depression of respiration were inseparably linked in dihydrocodeine as they are believed to be in the common analgesics.

Enzyme Treatment of Arteriosclerosis.—A series of 6 patients suffering from intermittent claudication and 20 who had obliterative arteriosclerosis were treated with Vasolastine, stored under optimal conditions, by Otto Selvaag and co-workers (*Nord. med.* 61:713-717 [May 7] 1959). This drug is a combination of citrogenase, amino acid oxidase, and tyrosinase. In two patients the treatment was abandoned. The remaining 18 patients received 22 to 160 injections over a period of 2 to 14 months. Five of the patients with intermittent claudication and one with angina pectoris improved during the period of treatment. The subjective improvement in two patients with claudication was especially good but even then arteriographs showed an increase of intimal lesions in the femoral arteries. Most probably the improvement was due to a more effective collateral circulation. The 18 patients who were treated for more than two months had a serum cholesterol value averaging 350 mg. per 100 ml. before treatment. At the end of the treatment the serum cholesterol value was 363 mg. per 100 ml. For the seven patients treated more than nine months, the figures were, respectively, 403 and 397 mg. per 100 ml. Changes were therefore insignificant in serum cholesterol values during or after treatment. There was no improvement in the arteriographs of the aortic, iliac, or femoral arteries. No immediate effect of the injections on the temperature of the skin and the muscles in the lower extremities was noted.

Transurethral Prostatic Resection.—At the Rikshospital in Oslo, transurethral resection is chosen for 80% of the patients with benign prostatic hyperplasia and retropubic prostatectomy is chosen for the rest. The choice of operation is largely determined by the size of the prostate and the wishes of the patients. To compare the respective merits of the two methods, Dr. W. Mathisen (*Tidsskrift for den norske Laegeforening,* July 1, 1959) made a five-year follow-up examination of 347 patients. Of the 258 who had had transurethral resection, 20% and, of the 89 who had had retropubic prostatectomy, 48% suffered from total retention of urine on admission. In the former group there were no operative deaths and in the latter there was one. In the former, 93% and in the latter, 83% had an uncomplicated postoperative course. Mathisen tempered his praise of transurethral resection with the warning that the procedure is technically difficult.

Nephrectomy.—The admission to the hospital of two comparatively young patients who had developed hypertension a few years after nephrectomy caused Mjölneröd and Prydz (*Tidsskrift for den norske Laegeforening,* July 1, 1959) to wonder what the long-term prognosis is with regard to blood pressure in such patients. They undertook a follow-up examination of 59 of these. The indication for nephrectomy was pyohydronephrosis in 24 patients, hydronephrosis in 19, calculi in 7, traumatic rupture in 5, hypoplasia in 3, and essential hematuria in 1. Of the seven with a high preoperative blood pressure the hypertension in two persisted after the operation. Of the remaining 52 patients with a normal preoperative blood pressure 12 developed hypertension. Though this investigation yielded no clear-cut answer to the questions raised, it suggested that hypertension may be anticipated in 20 to 25% of the patients on whom nephrectomy is performed for unilateral disease.

Acute Osteomyelitis.—Dr. K. Stray (*Tidsskrift for den norske Laegeforening,* July 1, 1959) reviewed a series of 32 patients who had acute osteomyelitis with special reference to the mistakes made before many of these patients were admitted to the hospital. In 19 they had long remained at home because some other ailment such as rheumatic fever or phlegmon of the soft tissues had erroneously been diagnosed, or because an early roentgenogram had been negative. Ten of these 19 had been given inadequate doses of penicillin which had only confused the issue and masked the correct diagnosis. In one patient the illness had lasted for 120 days and in another it had lasted for 63 days before admission. In spite of such delays, and because of the penicillin given in large doses over a long period, there were no deaths. A follow-up examination showed that 31 of these patients had recovered completely. The one exception was a patient who had had a series of abscesses lasting a few days and recurring at long intervals.

Relapsing Gonorrhea.—Dr. H. C. Gjessing (*Tidsskrift for den norske Laegeforening,* July 1, 1959) stated that since 1952 there has been a marked rise in the frequency of relapses after the treatment of gonorrhea with penicillin. Although the same preparation and dosage was used, the relapse rate rose from about 2.3% at the end of 1954 to about 10% at the end of 1957. Evidently the dosage of 300,000 units had become insufficient, and since January, 1958, the dosage has been raised to 600,000 units of procaine penicillin. Since September, 1958, the penicillin resistance of the causative organism has been determined before treatment is given.

SPAIN

Contest for Blanco Soler Prize.—Physicians of any country in the world are entitled to enter this contest but their writing must be in Spanish. The manuscript must be typed double space, on only one side of the paper, and be over 100 pages long. The topics to be treated are problems of art, history, literature or philosophy, and their relation to medicine. Each monograph must have a title and be accompanied by a sealed envelope containing the same title as the monograph and the author's name. Therefore, no work should be signed or include any indication of the author's identity. The monographs for this contest should be bound or simply have the pages sewed together. They should be sent in duplicate, by registered mail to Dr. Don Juan Fernán Perez, Secretary General, calle de Fuencarral, 113—Madrid. The closing date for entering this contest is Nov. 30. The presentation of prizes will be made during the inaugural meeting of the Association of Physician Writers and Artists in the assembly room of the Official College of

Doctors, Madrid—calle de Esparteros, 11. The first prize is 5,000 pesetas and a gold medal. The second prize is 2,500 pesetas and a silver medal. For honorable mention bronze medals will be awarded.

UNITED KINGDOM

Parking Privileges for Doctors.—Doctors are to have curbside parking space reserved for them and will be issued badges for their automobiles, the annual meeting of the British Medical Association (BMA) in Edinburgh was told by the chairman of the Private Practice Committee. The BMA has been assured of support from the Ministry of Transport for reservation of space outside or near surgeries and hospitals in controlled parking zones. Badges will be issued to those who use cars for house calls or visits to establishments where there is no parking lot. Local authorities will be urged to exempt doctors from excess charges on parking meters when they have been required to stay with patients longer than the permitted parking period.

Family Frictions and Divorce.—At the same meeting, leading London psychiatrists agreed that it was not a bad thing for children to see their parents quarrel in a civilized way and make up. If inoculated with small doses of parental disharmony, children become immunized and realize that this kind of thing can happen in marriage. Concealment of parental disharmony, said Dr. D. Stafford-Clark, might result in a build-up of tensions. Then the children will see, not the long-stoked fires of resentment but the holocaust that burns down the house. If parents can quarrel and make up in front of the children their marriage will stand a better chance and the children will grow up to realize that minor quarrels do not lead to divorce. Every marriage worth saving has headed for the rocks at some period.

Rapid Growth, Short Life.—At the same meeting, Prof. P. L. Krohn, of Birmingham University, said that people age fastest when they are youngest and begin to age more slowly as they get older. A diet giving the maximum rate of growth is not the best for a long life span. Rapid growth and short life go together.

Alternative to National Health Service.—At the same meeting, an alternative to the National Health Service was discussed. The cost of the scheme would be met in part by the state and out of insurance funds. Doctors would be paid for each service that they rendered. Control would be by an independent body on which the medical profession, the public, the government, and recognized insurance agencies were represented. The association's council, representing more than 72,000 doctors, was instructed to approach other professional bodies about the formation of a confederation of professional associations. Dr. E. A. Gerrard said that, while the influence of the trade unions and big business had steadily increased, that of the professional classes had tended to diminish. The proposed confederation should be free from party politics.

No New Hospitals.—At the same meeting, attention was called to the fact that not one new general hospital had been completed in Great Britain since the National Health Service started. The policy of the Ministry of Health has been one of patch and mend. The hospital standards are rapidly falling behind those of almost all the countries of Western Europe. If this continues it is inevitable that the standard of medical service will also deteriorate.

Patients Outnumber Population.—The number of persons on doctors' lists in London last year, 3,449,601, was 224,601, or nearly 7% more than the 3,225,000 estimated to live in the area. This is stated in the 11th annual report of the London Executive Council of the National Health Service. The inability to identify persons who died, emigrated, or joined the armed forces accounted for much of this inflated figure. About 50% of those reported as treated were without a health service number. Much of the inflation arose from immigration. As a result of inquiries among immigrants who had been registered with a doctor for more than a year, many were being removed from lists for such reasons as "returned abroad" and "whereabouts unknown." The report gives details of visitors from 59 countries who were treated. People from Eire, Australia, the United States, Germany, South Africa, India, Canada, the West Indies, East Africa, West Africa, and France topped the list.

Federation Wants Doctors.—The Central African Federation's senior medical officer hopes to persuade the government to cut the element of risk for young medically skilled immigrants by guaranteeing free return air transportation for interns, who, on completing a year's work, are told that the federal medical service will not provide the career they seek. Rhodesia and Nyasaland suffer from a shortage of skilled medical staff, largely because Africans now seek treatment which they used to regard with deep suspicion. Thus, although the number of the Federal Ministry of Health's medical officers rose from about 200 to about 240 during the five years ending in 1958, in the same period admissions of African inpatients were almost doubled.

Sensitivity to Poliomyelitis Vaccine.—Streptomycin and penicillin are used in the manufacture of poliomyelitis vaccine from infected monkey kidney cultures, and although the possibility of allergic reactions to the vaccine has always been considered no case had been reported in Britain until Thomson and Fletcher (*Brit. M. J.* 2:39, 1959) described an immediate sensitivity reaction to the vaccine in a nurse. Within five minutes of receiving an injection intramuscularly she felt a generalized itching, particularly about the eyes, which began to swell until she could hardly see. She had a throbbing sensation in her ears, abdominal cramps, and symptoms of shock. An injection of 1 ml. of 1:1,000 epinephrine solution was given subcutaneously which gradually relieved the condition. Because of her occupation and youth it was decided to complete the immunization six weeks later. A course of injections of 0.1 ml. of poliomyelitis vaccine was planned at weekly intervals. These produced periorbital edema, nausea, agitation, and trembling, but the symptoms subsided within 10 minutes after administration of epinephrine and chlorpheniramine maleate. It was estimated that only 3 to 10 units of penicillin and 20 units of streptomycin were present in 1 ml. of the vaccine.

The authors recommend that, before poliomyelitis vaccine is given, the patient or the parent should be asked if there is a history of penicillin or streptomycin sensitivity and that if there is any doubt a test dose should be given intradermally. Particular attention should be paid to those who work with these antibiotics. If available, penicillinase should be given several hours before the vaccination.

Installation of the President.—Because the Duke of Edinburgh was still in Canada during the Joint Annual Meeting of the British and Canadian medical associations in Edinburgh in July, his installation as President of the British Medical Association was postponed until the autumn. The ceremony will take place in BMA House on Oct. 28, and in the evening the Duke will be present at the council dinner of the association. In his absence the following message was read:

"When I accepted your invitation to become President of the British and Canadian Medical Associations, I had every intention to be present at the joint meeting in Edinburgh. However, as I am sure you know only too well, nothing in this life is entirely certain, and I am at present in Canada due to circumstances quite beyond my control. I am particularly sad not to be with you, because this meeting of British and Canadian medical men is just that kind of Commonwealth cooperation which can do the most good. The meeting together of men of like minds, working to the same end, demonstrates the value of the Commonwealth connection and uses it to achieve practical results.

"Although I have to miss the joint meeting in Edinburgh, I have had the privilege of being installed as President of the Canadian Medical Association in Toronto only a short while ago. This was a most pleasant and successful affair, which I am sure my Deputy President, Dr. Kirk Lyon, will confirm. Later this year I look forward to my installation as President of the British Medical Association. As I understand that it is customary for the president to deliver a short address on that occasion, I do not propose to anticipate that task today. This is simply a short message of apology and encouragement in my unavoidable, but still regrettable, absence. I hope very much that you will all enjoy the present meeting and that the arguments will be fierce and long. There is no better way to find out the strength of opinions and ideas than open and unfettered discussion. It is also my hope that the whole meeting will take place in a happy and cooperative atmosphere, because it is bound to color the outlook of all those who are attending for the next 12 months, and, speaking as a customer, I would rather be attended by someone who had been inspired by happy and lively conference than depressed by a series of dull debates. I wish the meeting every success."

Trachoma.—It is hoped that means to prevent or cure trachoma will result from discovery of the causal agent. Isolation of the causative virus was achieved by Dr. L. H. Collier and Mr. J. Sowa, working in Gambia. The virus had been found a little earlier in Peking, but the British workers were the first to demonstrate that it caused trachoma in man. The virus was inoculated into the conjunctiva of a blind volunteer and resulted in typical trachoma.

Delivery by Suction.—According to an annotation in the *British Medical Journal* (July 18, 1959) the replacement of traction forceps by an instrument using suction was considered even before 1849. Recently the vacuum-extractor of T. Malmstrom, of Gothenburg, has given fresh impetus to the idea. The instrument consists of a suction cup attached by a chain to a metal traction handle and connected to a vacuum pump and meter. The cup, which is made in four sizes from 55 to 80 mm. in diameter, is applied to the fetal scalp, and a vacuum of 0.6 to 0.8 kg. per square centimeter is formed. Traction is then applied intermittently in time with the uterine contractions.

W. D. Cunningham, of Sydney, Australia, used the vacuum-extractor in a series of 21 patients in preference to the conventional forceps. He was impressed by the fact that excessive or ill-directed traction was impossible because the suction cup would come away if the surface to which it was applied was not relatively flat or if the force exerted exceeded that of the suction. Moreover, the compression action of ordinary forceps was absent.

O. G. A. Berggren, of Linkoping, Sweden, reported that in a 12-month period of 1956-1957 before the vacuum-extractor was introduced the cesarean section rate of delivery was 2.1% and the forceps rate was 3%. In the following 12 months the vacuum-extractor was used in 75 deliveries (4.6% of the total), and the cesarean section rate fell to 1.3% while forceps were applied only once. The most common indications for employing suction were fetal distress and failing uterine contractions, but, whereas Cunningham used the vacuum-extractor only when the traditional conditions for forceps extraction were fulfilled, Berggren used the instrument in eight deliveries before the cervix was fully dilated and in six while the head was still high. Berggren is convinced that the vacuum-extractor is less hazardous to mother and baby than conventional forceps. The artificial caput succedaneum which the suction cup caused usually disappeared within a day, and in only 10 of the 75 babies was the mark still apparent after a week. There was no increase in the incidence of intracranial damage to the fetus after the introduction of the new instrument.

Life in the Frozen or Dried State.—Parkes and Smith (*British Medical Journal,* May 16, 1959) stated that suspended animation is achieved in nature by dessication more often than by freezing and that the ultimate aim of all biologists engaged in the preservation of life at low temperatures is to graduate from freezing to freeze-drying, so that the material can be kept on the shelf, rather than in the freezer. Life depends essentially on a cycle involving water, oxygen, carbon dioxide, fixed nitrogen, and a temperature at which interaction is possible. Many lower organisms and most plants produce spores or seeds which have a very low water content and a negligible respiration rate, and thus have a high resistance to cooling, drying, and lack of oxygen.

Young or hibernating warm-blooded animals have something in common with cold-blooded animals in that their body temperature can be reduced to a few degrees above 0 C without damage. The hibernating bat can survive at several degrees below zero provided it does not freeze. In all these cases, however, heartbeat and respiration still proceed slowly, so that the state is not one of suspended animation. There is no evidence that the cold-blooded vertebrate or the young or hibernating warm-blooded animal has any immunity to the damage caused by conversion of body water to ice. In adult nonhibernating mammals the position is still more difficult because breathing and circulation cease when the internal temperature is reduced to between 25 and 15 C. When cooled below that range the respiration and circulation cease and death was supposed to be inevitable. This is now known not to be so, and by special methods mice, rats, dogs, and monkeys have all been revived from deep body temperatures approaching 0 C after cessation of breathing and heartbeats for up to one hour. Recovery is usually complete and tests on resuscitated rats have shown no impairment of memory or learning ability following the severe anoxia. Dogs and monkeys showed no change in reflexes or in behavior.

In the hamster, a potential hibernator, the body temperature was reduced to less than zero by immersion in a bath at —5 C. In these circumstances the animal may start to freeze, or it may supercool. In the freezing animal, body water begins to be converted to ice in the superficial tissues, in which case the deep body temperature drops only slowly below the freezing point of the blood (—0.6 C). Such animals have been resuscitated undamaged after the body temperature has been below the freezing point for up to one hour, at which point about 50% of the body water had been converted to ice. During supercooling the body temperature is not maintained by the latent heat of crystallization of water, and falls rapidly to that of the surrounding bath. The supercooled state may be terminated by the sudden crystallization of ice throughout the tissue fluids, which results in a rapid rise of body temperature to freezing point and is very dangerous to life. If spontaneous crystallization does not occur, supercooled animals can be revived in perfect condition.

In man, body temperature is now commonly reduced to about 28 C for surgical purposes, but at this temperature the heart still beats slowly, and natural breathing can, if necessary, be supplemented by artificial respiration. Recently, Niazi and Lewis reported that a patient had survived cooling to a deep body temperature of 9 C without circulating her blood through a pump oxygenator. The heart was at a standstill for one hour. After rewarming, the patient recovered consciousness and survived 38 weeks thereafter without any apparent alteration in neurological or intellectual functions. Before treatment she had been in the terminal stages of inoperable pelvic carcinoma with abdominal and pulmonary metastases. She eventually died from the spread of the original disease. This temperature (9 C) is the lowest recorded in a human adult who subsequently recovered. Temporary cooling to this degree may prove of great value in medicine and surgery.

New Hypotensive Agent.—The medical treatment of malignant hypertension has hitherto been based on the use of drugs blocking transmission at the synapses of the autonomic ganglions. While they block preganglionic sympathetic impulses, and so reduce blood pressure, they also block preganglionic and postganglionic parasympathetic action, and for this reason produce such undesirable side-effects as constipation, blurring of vision, and dryness of the mouth. Professor Rosenheim and co-workers have used a new type of hypotensive drug, bretylium tosylate, which selectively accumulates in adrenergic nerve endings in sufficient concentration to block adrenergic (peripheral sympathetic) transmission, without antagonizing the direct action of circulating epinephrine and levarterenol (*Lancet* 2:17, 1959). It thus produces a fall in blood pressure without undesirable side-effects, on either the sympathetic or the parasympathetic systems. Animal studies by Boura showed that it produces a generalized blocking of the sympathetic nervous system in doses that do not inhibit parasympathetic activity or interfere with transmission in the central nervous system. Studies with the drug labeled with radioactive carbon (C^{14}) showed that its high specificity of action is probably the result of selective accumulation in adrenergic nerves. Unlike such drugs as phentolamine, bretylium is not adrenolytic.

Observations on normotensive volunteers and hypertensive patients showed that the new drug effectively reduces blood pressure and can be used for the long-term treatment of hypertension. The effective dose varies widely from person to person (130 to 840 mg. three times a day by mouth). A series of 24 hypertensive patients were thus treated, some for six months, with excellent results. Hourly blood pressure records showed that control of blood pressure was fairly smooth if the drug was given every eight hours. The hypotensive effect of bretylium is potentiated by chlorothiazide. The only side-effect observed was transient congestion of the nasal mucosa in some of the patients. Tests with C^{14}-labeled bretylium showed that a single dose of the drug is completely eliminated in 24 hours.

Continuous Blood Pressure Monitor.—A new continuous blood pressure electronic monitor, invented by Dr. J. H. Green of the department of physiology, Middlesex Hospital Medical School, London, is now in commercial production. Not only does it enable physicians to obtain a continuous reading of a patient's blood pressure but also it will regulate the supply of drugs to the patient to maintain a predetermined blood pressure level. The blood pressure follower, as it is called, has been in use for the last 18 months in the operating room of a London hospital.

Instead of the usual method of using an arm cuff and a stethoscope to listen to sounds in the artery distal to the cuff, the new instrument requires only a small cuff containing a crystal microphone that is fitted over the patient's finger. The main disadvantage of the arm cuff method is that it causes discomfort to the patient if left on for any length of time and that the stethoscope can be used only in quiet surroundings and provides only spot readings. Another method, in which a cannula is inserted into an artery, also causes discomfort and carries with it the danger of clot formation in the artery. The new method is painless and can be used while the patient is asleep, when the necessary information may be relayed to a remote point such as a nurses' office. Any abnormal change in pressure immediately alerts an alarm system and bells or lights will give warning at the control point.

One of the main principles on which the instrument is based is the use of a finger as the source of pulsation. A piezoelectric crystal, which acts as a microphone, is placed over the digital artery. The finger is then inserted in a cuff and the cuff is enclosed in a rigid plastic tube. The cuff is then inflated from a small pump in the apparatus. The piezoelectric crystal responds to variations in the digital pulse and the impulses from the crystal are used to control the pressure in the cuff and thus provide a continuous recording.

An electromagnetic valve opens and closes with the pulsations. A fixed leak deflates the cuff when arterial pulsations stop as the pressure in the cuff exceeds systolic arterial pressure. The electromagnetic valve then opens automatically, more air is pumped into the cuff, the cycle is completed, and then repeated for any required period. The cuff pressure in this way follows changes in systolic blood pressure and all such changes are revealed on the instruments of the apparatus. An important principle of the procedure is the insertion of the entire finger into the rigid plastic tube which contains the pneumatic cuff. By this means the risk of edema is minimized when used over a long period. Moreover, the cuff can be worn for many hours without discomfort and records can be obtained over still longer periods merely by changing the finger used every four hours or so.

One of the invention's main advantages is that it enables a continuous trouble-free record of blood pressure changes throughout an operation or in the ward. With this instrument, it is also possible to pre-set the required blood pressure level for as long as required, and a solenoid device automatically controls the intake of drugs, so that blood pressure constantly remains at the required level. Any variation from the predetermined maximum and minimum automatically sets off an alarm immediately, at the same time cutting off the supply of the drug. In patients with shock in whom the blood pressure and the impact of the shock are closely related, the instrument provides constant observation and gives prior warning of dangerous changes in blood pressure level. This information is of great value especially if blood transfusions have been given.

There is a large potential use for this apparatus in the field of psychiatry. This is not a so-called lie detector, but practitioners in the treatment of mental ailments should welcome this means of recording emotional responses, relative to changes in blood pressure. One big advantage of the instrument is the fact that it can be used so unobtrusively. Eliminating the emotional stress usually induced by direct contact with the consultant, it can be used to record away from the room where the patient is relaxing.

CORRESPONDENCE

VETERANS' NON-SERVICE-CONNECTED DISABILITIES

To the Editor:—The Medical and Chirurgical Faculty of the state of Maryland (Maryland State Medical Association) has, for many years, expressed concern over the inroads the Veterans Administration hospitals are making into the realm of the private practice of medicine. In order to combat the fantastic growth of treatment of non-service-connected ailments of veterans, the faculty has passed many resolutions condemning this practice and urging that something concrete be done to curtail or stop this insidious growth. The faculty's House of Delegates at its 1959 annual meeting passed a resolution that all component medical societies of the American Medical Association be contacted and urged to support the faculty's stand in this respect.

As a result of a letter sent to every A. M. A. component medical society, 11 answers have been received, all in the affirmative. It is anticipated that other societies will also reply in the affirmative and that full support to this projected concerted action will be forthcoming from them as well. It is hoped that an appropriate resolution will be introduced in the A. M. A.'s House of Delegates at its clinical session in Dallas in December.

Amos R. Koontz, M.D., Chairman
Committee on Veterans' Medical Care

MEDICAL FILM REVIEWS

Hands: Psychiatric Occupational Therapy: 16 mm., color, sound, showing time 28 minutes. Prepared by Jackson A. Smith, M.D., Omaha. Produced in 1958 by and procurable on loan from Audio Visual Aids Section, Nebraska Psychiatric Institute, Omaha 5, Neb.

It is a regrettable fact that only a few deeply empathic character actors can undertake the portrayal of a psychiatrist, a mental patient, or a professional psychiatric aide without becoming strained, stilted, or overtheatrical in manner, gesture, or voice. This almost universal handicap applies also to this film but, happily, it has few other defects. In substance it relates how a young schizophrenic woman is induced to explore and express her relationship with people past and present by molding a series of clay figurines in the occupational therapy section of a mental hospital, and how this form of communication is utilized therapeutically by the occupational therapy worker under frequent psychiatric supervision. True, the figurines purportedly carved by the patient are actually minor masterpieces of mimetic art, and the sequences omit mention of any other concurrent therapy; yet, this glorification of a single aspect of the treatment makes the film's message all the more vivid. The author's script is clear and psychiatrically sound, the color photography is superb, and the musical background unobtrusively expressive. The film, even without expert introduction or subsequent commentary, is recommended for exhibition to lay and professional groups interested in ancillary techniques in psychotherapy.

NEW FILMS ADDED TO A. M. A. MOTION PICTURE LIBRARY

The Operating Microscope in Otologic Surgery: 16 mm., color, silent, showing time 24 minutes. Prepared in 1958 by George E. Shambaugh, M.D., Eugene L. Derlacki, M.D., and Wiley H. Harrison, M.D., Chicago. Procurable on loan (service charge $4) from Motion Picture Library, American Medical Association, 535 N. Dearborn St., Chicago 10.

The history of the development of the operating microscope is traced with unposed photographs of the persons who were chiefly responsible for this innovation. Examples of the use of this instrument in reconstructive surgery of the middle ear are shown. (Reviewed in J. A. M. A., December 6, 1958, page 1935.)

Stapes Mobilization, Footplate Visualization Method: 16 mm., color, silent, showing time 11 minutes. Prepared in 1956 by George E. Shambaugh, M.D., Eugene L. Derlacki, M.D., and Wiley H. Harrison, M.D., Chicago. Procurable on loan (service charge $3) from Motion Picture Library, American Medical Association, 535 N. Dearborn St., Chicago 10.

The original, relatively blind, tactile method of mobilizing the stapes has been changed to a more exact controllable technique by direct visualization of the footplate under the operating microscope. The method of exposing the footplate to direct inspection and several methods of achieving mobilization are demonstrated. (Reviewed in The Journal, June 1, 1957, page 601.)

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Radioiodine Therapy of Hyperthyroidism. G. E. Sheline and E. R. Miller. A. M. A. Arch. Int. Med. 103:924-932 (June) 1959 [Chicago].

The authors report on 431 patients with hyperthyroidism, who were treated with radioiodine (I^{131}) at the University of California Medical Center in San Francisco between September, 1945, and June, 1957. Of the 431 patients, 324 had hyperthyroidism with either diffusely enlarged or normal-sized thyroids; 78 patients had thyrotoxicosis recurrent after subtotal thyroidectomy; and 29 patients had toxic nodular goiters. Although thyroidectomy was considered the treatment of preference in these patients, they were treated with I^{131} either because of refusal of, or medical contraindication to, surgery. A number of patients in each category had had some previous therapy with one of the antithyroid drugs; however, it had been discontinued several weeks or months before the institution of I^{131} therapy. Patients of all ages appeared in the toxic diffuse and postsurgical recurrent goiter groups, whereas all patients with toxic nodular goiters were 40 years of age or older. Patients were placed on sedation, dietary regimen, vitamin supplementation, and other supportive therapy as necessary and were seen at monthly intervals. The patients were retreated at intervals of about 2 months until hyperthyroidism was controlled.

In 95% of the 431 patients the toxicity was controlled with I^{131}; therapy in the other 5% was incomplete. Thyrotoxicity was controlled in 59% by one dose of I^{131}, and 61% became euthyroid within 3 months. Hypothyroidism developed in 17%, and there was recurrence in 3% of the patients with toxic diffuse goiters. Exophthalmos may improve, appear, or progress after I^{131} therapy. Although comparison is difficult, it would appear that in this respect the results are about the same or are slightly better than after surgical subtotal thyroidectomy. Orbital decompression became necessary in one patient, but in no patient was vision lost. There was one unexplained death 3 weeks after treatment with I^{131}. Three patients under 20 years of age developed thyroid nodules 5 or more years after therapy.

The Role of Benign Esophageal Obstruction in the Development of Carcinoma of the Esophagus. R. A. Joske and E. B. Benedict. Gastroenterology 36:749-755 (June) 1959 [Baltimore].

Of 1,026 patients with disease of the esophagus who were admitted to the Massachusetts General Hospital in Boston between 1947 and 1956, 554 had carcinoma and 472 had benign esophageal obstruction; carcinoma later developed in 13 of the 472 patients. The form of benign esophageal obstruction which was initially present in these 13 patients, between the ages of 35 and 78 years, consisted of esophageal web in 4, lye stricture in 3, achalasia of the cardia in 3, and peptic stenosis, congenital stenosis, and benign stenosis of unknown origin in 1 patient each. There were 7 men and 6 women. In all the patients the stricture had been present for many years before the development of carcinoma, the average duration of symptoms being 30 years in women and 30.7 years in men. The earlier development of carcinoma in the men was due to an earlier occurrence of esophageal obstruction and not to the endocrinologic environment in which the tumor developed.

In 11 of the 13 patients it was possible in retrospect to observe a change in the clinical aspect concomitant with the development of carcinoma, and from this to ascertain what symptoms in a patient with esophageal obstruction should be regarded as suspicious and investigated further. In 5 of these patients the first symptom of carcinoma was the return of dysphagia after a prolonged period of relative lack of symptoms, ranging from 21 to 50 years. In 6 patients carcinoma developed while regular treatment of the benign obstruction was being carried out, and without an interval of freedom of symptoms. All these patients had continued dysphagia. Dysphagia was thus an important symptom in all 11 patients. Loss of weight was the next most frequent symptom and was noted in 9 patients. Pain was not prominent, being stressed only by 6 patients. In 3 of these, pain was not due to esophageal obstruction, but to secondary pneumonia. Physical examination was of direct diagnostic help in one patient in whom a high carcinoma with infiltration had immobilized one vocal cord.

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Three patients had aspiration pneumonia. None had severe anemia. A correct roentgenologic diagnosis of carcinoma was made in 3 of 9 patients; in 2 patients roentgenologic examination was not performed, as the diagnosis was already established by other means. The diagnosis of esophageal carcinoma was correctly made by esophagoscopy in 7 of the 11 patients. Biopsy confirmation of carcinoma was obtained in 9 patients. Despite early diagnosis and the fact that in most patients carcinoma developed while the patient was under direct medical observation, the prognosis was poor. Ten of the 13 patients are known to be dead.

Carcinoma of the esophagus is an unusual but definite complication of benign esophageal obstruction. Its incidence is particularly high in patients with esophageal web and lye stricture. It also occurs much more frequently in patients with achalasia and peptic stenosis than in the general population. There is no characteristic clinical syndrome due to this combination. Recurrent or persistent dysphagia in a patient with benign obstruction merits further investigation with roentgenologic examination, esophagoscopy, and biopsy after careful preparation of the esophagus. The bad prognosis of these carcinomas can be improved only by awareness of the possibility of carcinoma in patients with benign lesions of the esophagus.

Radioactive Fat Absorption and Clinical Response of Sprue to Steroid Therapy: Report of Three Unusual Cases. C. H. Brown, O. Glasser and E. J. Kurt. Gastroenterology 36:760-769 (June) 1959 [Baltimore].

The authors report 3 unusual cases of sprue in women, aged 24, 49, and 39 years respectively. Each patient had diarrhea and a low serum albumin content and was malnourished. Two patients had hypocalcemia, tetany, and osteoporosis; 2 had edema; and 1 had bleeding with an increased prothrombin time (180 seconds) which became normal 8 hours after vitamin K was given intravenously. Radioiodine-tagged triolein and oleic acid curves showed poor absorption and "flat" uptake curves for all 3 patients. None of the patients responded clinically to standard treatment, including the gluten-free diet, vitamin B_{12} given intramuscularly, and other measures. The patients then were given prednisone, in doses of 5 mg., 3 or 4 times daily for one week, to which they responded. Repetition of the radioactive fat studies after steroid therapy showed great improvement in the absorption of fat, paralleling the clinical response. Steroid therapy would seem indicated for patients with sprue who do not respond to other treatment.

Since many patients with sprue may not have the typical symptoms and signs of the disorder but its complications, diagnosis is difficult, and the diagnostic technique is one of exclusion. Radioactive fat studies of such patients can be of help, because they uniformly show poor absorption with "flat" uptake curves. Determination of the uptake of radioactive triolein and oleic acid is a dependable, simple, and objective measure of fat absorption. Radioactive fat studies can be of aid not only in the diagnosis of sprue but also in determining the response to treatment.

Malabsorption Syndrome: Review with Special Reference to Primary Malabsorption. P. Eilersen. Ugesk. læger 121:519-526 (April 2) 1959 (In Danish) [Copenhagen].

The malabsorption syndrome consists partly of symptoms with known etiology and well-defined pathoanatomic basis, partly of symptoms where etiology, pathogenesis, and pathoanatomic conditions are more uncertain. The term applied to the last-named cases is "primary malabsorption." Gluten-free diet, with avoidance of gluten of rye and wheat flour, is recommended. It can in many cases result in complete disappearance of the symptoms of primary malabsorption. The effect may not appear till late, and the diet must not be given up before 6 or 8 months. Adrenocortical steroids should be given only when the diet treatment does not give the desired result.

Myxedema as Complication in Pancreatogenic Steatorrhea. P. Eilersen. Ugesk. læger 121:526-528 (April 2) 1959 (In Danish) [Copenhagen].

The simultaneous occurrence of myxedema and steatorrhea seems to be unusual. In the course of a year a grave steatorrhea with resulting deficiency symptoms developed in a man, aged 57 years. The picture was complicated by a definite myxedema. Examination revealed pancreatogenic steatorrhea, and the course of the disease showed that all the symptoms, also the myxedema, could be explained as secondary to the pancreatogenic steatorrhea. After a month's treatment with pancreatin, protein, calcium, iron, and vitamins, the condition of the patient was miraculously improved. The treatment has lasted a year, and the patient continues free of symptoms.

Steatorrhea as Result of Diabetic Neuropathy in Gastrointestinal Canal. P. Eilersen. Ugesk. læger 121:530-532 (April 2) 1959 (In Danish) [Copenhagen].

A detailed report is given of 2 cases of steatorrhea and neuropathy in patients with grave diabetes. Chronic diarrhea as complication in diabetes has been described several times in the last 25 years. Especially characteristic are nocturnal watery diarrheas which occur when the diabetes has lasted a number of years. The intestinal symptoms are attributed to the results of visceral neuropathy.

This form of diarrhea is seen only in patients with other signs of a diabetic neuropathy which affects the autonomic nerves of the gastrointestinal tract.

Pyloric Ulcer with Special Reference to the Gastric Secretory Pattern.

R. W. Lopes, W. L. Palmer and J. B. Kirsner. Gastroenterology 36:790-795 (June) 1959 [Baltimore].

Of 1,076 patients with peptic ulcers seen by the authors in the course of 5 years, 60 (5.5%) were selected in whom the lesion seemed to be located roentgenologically in the pylorus or on either "slope" involving the pylorus. Of the 60 patients, 10 were not included in the statistics concerning gastric secretion, because the gastric secretory patterns were not available. Of the remaining 50 patients, 9 were women, between the ages of 44 and 78 years, and 41 were men, between the ages of 19 and more than 60 years; the greater number of patients were in the 5th and 6th decades, there being 15 patients in each group. Gastric secretory determinations were obtained from these 50 patients by collection of the secretion for one hour under basal conditions and by collection for a second hour after stimulation with 0.5 mg. of Histalog per kilogram of body weight.

Forty-seven (78.3%) of the 60 patients had typical ulcer distress; atypical pain patterns were present in 13 patients (21.7%). Nausea was observed in 18 patients (30%), and vomiting in 25 (41.6%). These findings suggested that there was no characteristic "pyloric syndrome." The gastric secretory patterns of the patients with pyloric ulcer were intermediate between those characteristic of gastric and duodenal ulcer. In the men, values of free hydrochloric acid ranged from 0 to 19 mEq. per hour in the basal study, and from 5 to 47 mEq. per hour after Histalog stimulation. In the women, basal values ranged from 0 to 7.4 mEq. per hour, and values after Histalog stimulation ranged from 1.9 to 15.5 mEq. per hour. The values in the female group were lower than in the male group, as in normal persons and in patients with gastric and duodenal ulcer. The importance of accurate localization of the pylorus and the use of definite terminology when referring to the pylorus are stressed.

The Clinical Significance of Blood Ammonia Levels in Laennec's Cirrhosis.

N. W. Chaikin and M. S. Konigsberg. Gastroenterology 36:785-789 (June) 1959 [Baltimore].

The authors studied the prognostic significance of variations in the blood ammonia levels and their relationship to protein intake in 73 patients with Laennec's cirrhosis, 27 of whom had cirrhosis with normal blood ammonia levels (group 1), 28 had cirrhosis with elevated blood ammonia levels and without neurological manifestations (group 2), and 18 had cirrhosis with neurological manifestations and elevated blood ammonia levels (group 3). Thirteen of the patients in group 1 remained on an unrestricted diet, and 14 were placed on a diet low in protein and high in carbohydrates. Most of the patients in group 2 were given a low-protein diet and vitamins; some of them were given a supplement of 15 Gm. of glutamic acid by mouth 3 times daily. The patients in group 3 were all given 25 Gm. of sodium potassium glutamate intravenously as an addition to 500 cc. of 5% dextrose in distilled water. As soon as the patients regained contact with their environment, 15 Gm. of glutamic acid was given orally 3 times daily. All the patients were placed on a diet low in protein and high in carbohydrates.

The results showed that the dietary regimen did not influence the clinical picture or the ammonia levels in the patients with cirrhosis in whom the blood ammonia levels were within normal range. In those patients with high blood ammonia levels but without neurological signs, a low-protein diet appreciably decreased the ammonia level and increased the survival rate, as compared with those patients who remained on an unrestricted protein intake. Patients with neurological manifestations and high blood ammonia levels also fared well with a low-protein diet in regard to the disappearance of the neurological signs and lowering of the ammonia levels. When glutamic acid was used as a supplement either orally or intravenously, the ammonia levels dropped more rapidly than when the patients were on a low-protein diet alone. High blood ammonia levels are clinically significant, both as therapeutic guides and from a prognostic point of view, whereas normal blood ammonia levels have no such significance.

Salmonellosis in Peru and the Secondary Complication of Human Bartonellosis or Carrión's Disease.

H. C. Arbulú and A. B. Soto. An. Fac. med. 41:685-702 (no. 4) 1958 (In Spanish) [Lima, Peru].

In a survey of salmonellosis in Peru (made in 1951-1957), the authors studied 4,654 cases of acute and chronic intestinal disorders and investigated the frequency of Salmonella and other intestinal pathogenic agents. This series included cases of meningitis associated with Sal. typhimurium in children, and of severe typhoid in dehydrated infants, observed at the same time that important epizootics occurred among domestic animals in Lima and adjoining areas. In the present investigation diagnoses were made by blood cultures and by studies of cerebrospinal fluid and feces, as well as material obtained at autopsies. Salmonellosis was found in 347 (7.7%) of the cases, sometimes with more than one strain, sometimes in association with Shigella or Staphylococcus organisms. The most frequent strain was Sal. typhimurium, although the trend in the last few years has been toward a marked decrease in the frequency of Salmonella organisms and an increase in the frequency of Shigella. The authors relate this change to the increasing use of antibiotics.

In the course of this investigation 9 new cases of complicated bartonellosis (Carrión's disease) were diagnosed. In all 9 patients the complicating infection was positively identified as salmonellosis, with Sal. typhimurium present in 4 of them. Patients with Carrión's disease (or verruga peruana, an autochthonous disease in Peru) become susceptible to salmonellosis of animal origin, which is a serious complication and may appear in the acute phase or at the beginning of or during convalescence. Infants too are susceptible, as was evidenced in this study. These findings point to the need for action against salmonellosis in Peru. Accurate laboratory and epidemiologic techniques should be used in fighting the disease.

SURGERY

Human Brain Changes in Cardiac Arrest. M. M. Mandel and R. G. Berry. Surg. Gynec. & Obst. 108:692-696 (June) 1959 [Chicago].

The authors describe observations on 2 women, aged 35 and 50 years, respectively, who experienced cardiac arrest. In the first case, the cardiac arrest was of 4 minutes' duration with a survival period of 27 hours, while the cardiac arrest, in the second instance, was of 8 minutes' duration with a survival period of 3 days. The cerebral changes in both cases exhibited a striking similarity but were more pronounced in the second case. The vulnerability of the cerebral cortex to acute anoxia is demonstrated by the changes in the occipital and frontal cortices. In these areas a laminar loss of cells was found, involving particularly laminas III and V, with the occipital cortex showing a greater degree of involvement in both cases. The calcarine area in the second case contained no normal-appearing neurons and exhibited dilated and proliferated blood vessels with an increased number of astrocytes and microglial cells in the cortex. The cerebellum was involved in both of the cases, showing a loss of Purkinje cells, as well as varying degrees of degeneration. Eosinophilic changes of the nucleus and cytoplasm were indicative of early anoxic changes. There was rarefaction necrosis of Bergmann's layer as well as an increase in glial elements. The molecular layer was prominent with microglia and astrocytes in the second case. The dentate nucleus was involved in both cases with loss of neurons and pallor of those that remained. The hippocampus was severely involved in case 2 with a marked loss of pyramidal cells in Sommer's sector. The basal ganglions in both cases and the pons in the second case revealed a diffuse loss of neurons throughout with dilated congested vessels.

These observations are of importance to the surgeon who is confronted with cardiac arrest during an operative procedure, for speed is essential in restoring circulation by cardiac massage. The crucial period for complete recovery is 3 minutes. With longer periods, selective involvement of the frontal lobe, occipital lobe, cerebellum, and hippocampus may occur, as described in these cases of cardiac arrest of more than 4 minutes' duration.

Indications and Contraindications to the Operative Treatment of Patent Ductus Arteriosus. F. H. Kutushev. Vestnik Khir. 82:29-36 (May) 1959 [Leningrad].

The author reports observations on 120 patients with patent ductus arteriosus, 102 of whom were subjected to ligation of the duct. There were 4 fatalities. Analysis of the late results suggests that patients below the age of 3 years should be operated on only if the patency of the duct has a deleterious influence upon the condition of the child. Best results from ligation were obtained in patients 3 to 15 years of age. Contraindications to the closure of the patent ductus arteriosus exist when complicated congenital malformations are present and the patency of the duct acquires a compensatory function. In some of the cases the closure of the duct may be done simultaneously with the surgical correction of other congenital anomalies. When a patent ductus is associated with a septal defect, the ligation has a favorable effect. The operative procedure on a patent ductus arteriosus in the presence of severe hypertension of the pulmonary circulation is particularly grave. However, operation can be successfully performed by a step-by-step narrowing of the lumen of the patent duct. A timely performed closure of the ductus arteriosus before the appearance of irreversible changes results in a good postoperative and late result.

Treatment of Malignant Edematous Exophthalmos by Implantation of the Pituitary with Yttrium 90: Report of Two Cases. G. M. Molinatti, F. Camanni and A. Pizzini. J. Clin. Endocrinol. 19:583-589 (May) 1959 [Springfield, Ill.].

Malignant edematous exophthalmos is generally attributed to excessive secretion of thyrotropin (TSH) or of a closely related material, called "exophthalmos-producing substance," by the pituitary. Exceptionally severe cases exist in which all forms of medical or roentgenologic treatment are unsuccessful, and progressive protrusion of the eyeballs, with consequent corneal and conjunctival changes, leads to blindness. The authors present the histories of 2 men, aged 61 and 47 years, respectively, who had malignant exophthalmos that proved refractory to the usual medical and roentgenologic therapy. They were treated by implantation of the pituitary with radioyttrium (Y^{90}). Prompt and marked improvement of the ocular symptoms occurred in both patients in association with normalization of thyroid function. These results have persisted in one case for at least 16 months after implantation; the other case was followed for only one month. No adrenocortical deficiency was observed. This effect of implantation of Y^{90} is interpreted as being due to selective radiobiological inhibition of the hyperactive pituitary cells which produce the thyrotropic hormone. In commenting on the selective inhibition of the cells that produce the thyrotropic hormone, the authors suggest that these cells, on account of their functional hyperactivity, could be more sensitive to irradiation than other cells.

Incidence of Metastasis in the Internal Mammary Chain in Operable Cancer of the Breast. E. Caceres. Surg. Gynec. & Obst. 108:715-720 (June) 1959 [Chicago].

The internal mammary lymph node chain was removed in 258 out of 261 women who were subjected to radical mastectomy for cancer by a surgical team in the Instituto Nacional de Enfermedades Neoplasicas, Lima, Peru. Data on the first 250 of these patients were tabulated and studied. The authors show that it is possible to perform a resection en bloc and in continuity of the breast, the contents of the axilla, and the internal mammary chain in an extrapleural manner. The operation described has not been followed by greater morbidity than the typical radical mastectomy. The operative mortality was less than 1%.

Only 92 (36.8%) of the patients were free from lymph node metastases. In 104 patients (41.6%) the axillary lymph nodes alone had metastases; in 48 (19.2%) both the axillary and the internal mammary lymph nodes were invaded; and in 6 (2.4%) the lymph nodes of the internal mammary chain alone were involved. Thus, the axillary lymph nodes were involved in 152 cases (60.8%), and the internal mammary chain nodes in 54 cases (21.6%). The study of the involvement of the internal mammary chain was extended to the first 4 intercostal spaces. The first intercostal space showed invasion by metastases in 37 of the 54 patients with internal mammary chain involvement. The greater incidence of metastases in this space in this series is presumably due to the resection of the first rib, permitting ligation of the internal mammary vessels almost at the upper edge of the first rib, and excision en bloc of the whole of the first intercostal space.

Whether or not radical mastectomy with resection of the internal mammary chain improves the results in the treatment of cancer of the breast cannot at present be affirmed. The author feels that the high incidence of metastases to the internal mammary chain in tumors located in the outer half of the breast (15.2%) justifies the extension of this type of operation to all mammary tumors, whatever their location. The operation should be carried out by experienced specialists.

Additional Contribution to the Utilization of the Internal Mammary Artery as the Organ of Revascularization of the Myocardium. F. Cataliotti. Minerva cardioangiol. 7:180-186 (April) 1959 (In Italian) [Turin, Italy].

This work concerns a series of 10 dogs which underwent a left internal mammary arteriocardiopexy for the purpose of studying surgical correction of diminished blood flow into the myocardium. The animals, after being anesthetized, were intubated with an endotracheal tube. The thorax was opened through the third intercostal space. The internal mammary artery was exposed and transplanted into the pericardium of the left ventricle, in which an incision had previously been made. Two grams of talc was spread over the pericardium. In order to produce a gradual degree of stenosis, cellophane was wrapped around the anterior descending branch of the coronary artery at 2 cm. from its origin. The transplanted internal mammary arteries were injected with an opaque substance to determine the presence of anastomoses from the arteriocardiopexy to coronary vessels.

Internal mammary arteriocardiopexy produced in most animals of this group anastomoses between the transplanted artery and the adjacent vascular area of the myocardium. Histological examinations revealed the presence of opaque material in the myocardial vasculature, which material had previously been injected into the mammary arteries. A satisfactory functional performance of the anastomotic channels between the systemic arteries and the coronary arteries was demonstrated on electrocardiographic examination. The results of this investigation are comparable to those of Litvak and Vineberg.

Comparative Observations on Operative Risks and Postoperative Course of Combined Valvulotomy for Mitral and Aortic Stenosis and of Aortic Valvulotomy Alone. R. Gentilli, E. De Giorgi and T. De Nunno. Minerva cardioangiol. 7:186-189 (April) 1959 (In Italian) [Turin, Italy].

The authors made a comparative study of operative risks and postoperative course in a series of 30 patients, divided into 2 equal groups; one group underwent a combined valvulotomy for mitral and aortic stenosis, and the other underwent aortic valvulotomy alone. The ages of the patients ranged from 7 to 52 years. There were 18 male and 12 female patients. A varying degree of calcification of the aortic valve and a difference in consistency of the myocardium of the left ventricle were the 2 most distinguishing pathological features between the 2 groups. There was a marked calcification of the aortic valve in 3 patients with aortic stenosis alone; the calcification was light and present in only one patient with both aortic and mitral stenosis. It was relatively easy to suture the incision of the ventricle in patients with mitral and aortic stenosis; this procedure was more difficult in patients with aortic stenosis alone.

The postoperative course in patients who underwent the combined operation was relatively uneventful, with no death recorded. The postoperative course in patients who underwent the operation for aortic stenosis alone was stormy, being characterized by the following single or combined symptoms: collapse, epistasis, and pleural effusion, requiring prolonged bed rest. There were 2 deaths in this subgroup. The authors conclude that the indications for combined valvulotomy for aortic and mitral stenosis are more favorable than those for valvulotomy for aortic stenosis alone in this series of patients.

Arterial Homografts in the Treatment of Peripheral Arterial Occlusions. L. E. Puech Leao, V. Khouri, J. Bueno Neto and A. G. Freitas Neto. Rev. paulista med. 54:348-356 (May) 1959 (In Portuguese) [São Paulo, Brazil].

Anatomic restoration of obstructed arteries is indicated whenever there is obstruction of any large artery and sympathectomy is insufficient to restore arterial flow in the muscles. The selection of patients for surgery must be based on the arteriographic findings. The prognosis is favorable when the obstruction involves only a segment of any large artery without impairing the permeability and free circulation above and below the segment obstructed. Arterial grafting is especially indicated in the cases of femoral obstruction which do not require manipulation of any important organ. Where there is obstruction in the aortic bifurcation, which calls for extensive laparotomy, the selection is much more restricted, especially for older patients or for those with generalized arteriosclerosis.

The department of surgery of the Faculty of Medicine, University of São Paulo, Brazil, has done intensive experimental studies with preservation of arterial grafts in alcohol. The 19 cases reported here represent the first surgical results obtained at the Hospital das Clínicas with this type of homograft. The 19 operations were performed between January and September of 1958. With the exception of one patient suffering from aortic-iliac chronic obstruction (Leriche's syndrome), all the transplantations were made for a femoral condition. Two patients had femoral wounds, one had thromboangiitis obliterans, and one was suffering from the sequels of embolism. The remaining 14 patients had femoral obstruction, with gangrene of the toes in 3 of them.

Fourteen patients recovered well. After an interval of 1 to 9 months after the operation, their grafts were functioning, and there were no symptoms of the vascular disorder for which they had been treated. In 5 patients the grafts did not function, and thrombosis occurred within 24 hours after the operation. In 2 cases the failure was attributed to errors in the surgical technique; these were the first patients in this series to be operated on. In the other 3 cases of failure, the indication for transplantation had been doubtful, for there was not enough free arterial circulation below the obstruction. In no case, however, was the patient worse than before surgery. The only death in this series occurred in a 79-year-old man and was not related to the operation. The patient died of cerebral thrombosis on the 11th postoperative day, although the graft was functioning and the arteries of the foot were pulsating during the whole postoperative period.

Adrenalectomy in Advanced Mammary Cancer. G. E. Block, A. B. Vial, J. D. McCarthy and others. Surg. Gynec. & Obst. 108:651-668 (June) 1959 [Chicago].

The authors point out that Huggins in 1951 had demonstrated that gratifying remissions could be obtained by removal of the adrenal glands in patients suffering from advanced mammary cancer. They themselves made studies on 27 patients who were subjected to adrenalectomy at the University of Michigan Hospital, Ann Arbor. They hoped to throw light on the physiological processes leading to remissions in these breast cancer patients and thereby to establish criteria for the selection of patients for adrenalectomy. Most patients were seen by the authors only after the diagnosis of advanced mammary cancer had been made. The majority of the patients had received some prior treatment for the breast lesions. The patients were observed before and after treatment in a weekly clinic conducted by the authors. No other significant treatment had been given for the mammary cancer within 6 weeks before the adrenalectomy. In all the patients who underwent adrenalectomy, the variable of ovarian function had been eliminated; 18 had undergone previous bilateral oophorectomy, 7 had been subjected to x-ray castration, and 2 of the patients were more than 18 years past the menopause. In this latter group, estrogen excretion studies indicated that what estrogen production remained was adrenal in origin and not ovarian.

The authors found that a rather random selection of patients for adrenalectomy will produce remissions in more than 40% of the patients. That this remission rate is real and worthwhile is demonstrated by the fact that many remissions were months and years in duration. The remission time alone (including patients who have not yet run the full course of their remission) was twice that of the total life expectancy of the group in which remissions were not achieved. Since this is an eventually fatal disease, the treatment is one of palliation and not of cure. The nature of adrenalectomy is such that, when success is not achieved, the surgeon and the patient are not left with a situation that remains in status quo. Instead, they are confronted with induced Addison's disease in the face of an advancing lethal neoplasm. Therefore, the authors feel that they can recommend adrenalectomy only for those patients who fulfill most of the following criteria: (1) tumor not involving the liver; (2) previous remission from oophorectomy; (3) high estrogen excretion; (4) "middle age" (preferably the 50's); and (5) prolonged duration of disease (more than 3 years). When considering the patient for adrenalectomy, all these facts must be considered individually and collectively.

Anatomicosurgical Contribution to the Systematization of New Surgical Techniques for the Decompression of Portal Circulation in Humans. F. Cataliotti and M. Bazan. Minerva chir. 14:427-432 (April 30) 1959 (In Italian) [Turin, Italy].

The authors carried out an experimental study for relief of portal hypertension in humans by connecting the vascular areas of 2 organs in the following 4 combinations: stomach-liver, spleen-liver, spleen-kidney, and kidney-descending colon. After performing a laparotomy, the organs were held together by making a continuous row of silk sutures on each organ. The sutures were tied before closing the abdomen. First method: Capsule of the lower surface of the liver lobe was connected with the serosa of the gastric wall at the edge of contact between the 2 organs. Second method: Capsule of the upper apex of the spleen was sutured to the capsule of the lower surface of the left liver lobe. Third method: Capsule of the lower apex of the spleen was sutured to the capsule of the upper apex of the kidney. Fourth method: A longitudinal incision of the peritoneum and a vertical incision in the serosa of the descending colon were performed, and the edges around the incision united by sutures. The latter procedure left a unique breach open; the external edge of the breach was then sutured to the capsule of the upper surface of the kidney. The organs were dusted with talc powder before ligating the sutures.

The results of this investigation were good. The surgical techniques for the decompression of portal circulation may be recommended, because both involve only a light surgical trauma and utilize an initial portal hypertension which facilitates creation of anastomotic channels. A roentgenologic and functional examination of the portal circulation should precede the operation in order to establish the optimum level of the derivation vessels. The spleen should not be used for this procedure if it is enlarged.

The Misuse of Antibacterials in Inguinal Herniorrhaphy. R. S. Myers. Surg. Gynec. & Obst. 108:721-725 (June) 1959 [Chicago].

The development of antibiotic-resistant bacteria, which is one of the chief causes of hospital infections, has been hastened by the unnecessary use of antibiotics in patients who have had no proved infection. Simple or uncomplicated inguinal hernia, in which there is no incarceration or strangulation of the intestine or other abdominal contents, is one condition in which infection is not expected to occur after surgical repair, provided that adequate aseptic surgical technique has been followed and the patients have been properly selected and prepared. This paper is concerned with a critical evaluation of the use of antibacterials in 1,536 inguinal herniorrhaphies, performed in 24 community hospitals located in 7 states and participating in the Medical Audit Program, developed by the American College of Surgeons and the Commission on Professional and Hospital Activities. This group of hospitals is above average in its attempts to observe high standards of patient care. The patients were evaluated by the medical staff of each hospital during the second quarter of 1958, and their impressions, which were recorded on standard Medical Audit check sheets, were subsequently transferred to punched cards and processed by business machines. Analysis of the resultant statistics provides the basis of this critique.

A diagram, which shows the percentage of inguinal herniorrhaphy patients given antibacterials in each of the 24 hospitals, reveals wide variation between hospitals; the range extends from 100 to 9.2%. There were 596 (or 38.2%) of the 1,536 patients who received antibacterials. It was found that 421 (or 74%) of the 569 patients with simple inguinal hernias receiving antibacterials received these drugs needlessly, that is for prophylaxis. Moreover, the drugs given in most cases, penicillin, streptomycin, and the tetracyclines, are probably without therapeutic value in the prevention of staphylococcic infections which are being encountered presently in hospitals. Such misuse of antibacterials not only exposes patients needlessly to the dangers of serious and even fatal reactions, but it also wastes much money and nurses' time.

If the 421 patients received the minimum of one dose a day for 5.1 days, then they received a total of 2,147 unnecessary doses. If the average cost to the patient for one dose of antibacterials is set at the low figure of 50 cents, and if these figures, together with the estimated time expenditure by nurses of 3 minutes per dose, are projected into the 5,546 general hospitals in the United States, it would mean a minimum of $247,000 of wasted money and 25,000 wasted nurse hours involved in the dispensing of prophylactic antibacterials needlessly to patients undergoing this one operation (inguinal herniorrhaphy) during the period of one year.

Treatment of Cancer of Rectum in Copenhagen District Hospital in Gentofte. O. Kapel. Nord. med. 61:689-691 (April 30) 1959 (In Danish) [Stockholm].

The cases of cancer of the rectum treated from 1946 through 1954 are grouped as cancer of the rectum and cancer of the rectosigmoid. In many cases from 6 months to 4 years elapsed before hospital treatment. An extended Lockhardt-Mummery operative method (abdominoperineal extirpation in 2 sessions) was applied in 65 cases of cancer of the rectum. From 1946 to 1950, 34 patients were operated on by this procedure, with 3 deaths; 21 patients were living from 3½ to 6 years after the operation; 19, after 5 years; and 9, after 10 years. From 1950 to 1954, 31 patients were operated on by the method, with one postoperative death from pulmonary embolism; 19 patients were living from 3½ to 6 years after the operation. On abdominoperineal operation, performed on 11 patients, 3 deaths occurred; 4 patients died after 1 or 2 years; 5 patients are living from 3 to 7 years after the operation. Three gravely affected obese patients were operated on by Hartmann's method; 2 patients died, and 1 is living after 8 years. Perineoabdominal extirpation was done in 8 patients, with 3 deaths from postoperative ileus, but the late results did not equal those after the Lockhardt-Mummery method. The extended Lockhardt-Mummery operation has given the best immediate and the best late results.

Of the 37 cases of cancer of the rectosigmoid, 26 were operable. Nineteen patients were operated on by anterior resection, with one death. Only 9 patients are living after periods of over 1 to 10 years; the others died of local recurrence or distal metastases. Hartmann's operation was employed in 7 cases of rectosigmoid cancer, with one postoperative death; 3 patients died of cancer, and only 3 are living from 3 to 7 years after operation. It is thought that more cases of rectosigmoid cancer should be included in the established operative methods applied in rectal cancer if the principle of radical removal of mesorectum with mesosigmoid sufficiently high is followed. Anterior resection should be reserved for especially suitable cases and for patients who do not consent to colostomy.

NEUROLOGY & PSYCHIATRY

Inclusion-Body Encephalitides. K. Weisse and W. Krücke. German M. Month. 4:147-150 (May) 1959 (In English) [Stuttgart, Germany].

A group of encephalitic disorders of varying duration but with constant clinical and pathological characteristics, including the presence of acidophilic nuclear inclusion-bodies in neurons and oligodendroglia, may be differentiated from the great number of so-called atypical encephalitic diseases. This group constitutes a new type which should be added to the encephalitic disorders. Although there can be several etiological factors as in the other types of encephalitis, the fact that the herpes virus has been isolated from the cingulate gyrus at autopsy in a patient representing a typical case of the new type of encephalitis indicates that infection with the herpes or related viruses may be of greater importance than previously assumed. The task of further investigation must be to recognize this entity from clinical signs referable to the anatomic areas known to be involved and to attempt to isolate the virus from these areas at autopsy. The described histological characteristics must be searched for and their relation to the demyelinating diseases clarified.

Leptospiral Meningitis. S. Saslaw and E. D. Swiss. A. M. A. Arch. Int. Med. 103:876-885 (June) 1959 [Chicago].

The authors report on 10 patients with leptospiral meningitis admitted to the Ohio State University Hospital, Columbus, between 1954 and 1958. Eight patients had the anicteric form and only one patient the icteric form of leptospirosis. One of the 8 patients died. The patients presented central nervous system manifestations, which varied from mild meningeal irritation to coma. Cerebrospinal fluid findings in leptospirosis are not diagnostic. The findings in this group varied from a normal fluid early in the course of the disease to mild pleocytosis and a mild increase in protein later. Sugar and chloride levels usually remained within normal limits, although there was a temporary depression of spinal fluid sugar in 3 patients. These findings plus the clinical picture of meningeal irritation lead to the consideration of a viral infection of the central nervous system, such as viral encephalitis or poliomyelitis, or tuberculous meningitis when the sugar is depressed.

Examination of the formed elements of the blood aids little in the diagnosis of leptospirosis, since there may be no change in the white blood cell count or a moderate leukocytosis. Clinical characteristics of leptospirosis appeared to be the sudden onset of the illness, severe myalgia, conjunctival injection, and fever. Macular or maculopapular eruption, as observed in one patient, is not uncommon. The rash at times may assume a petechial character. All the patients had negative findings by virus isolation and viral serologic methods. Correct diagnosis of leptospirosis relies to a great extent on leptospiral agglutination tests. Evaluation of serial blood samples with a rising titer is the best evidence for present infection. Treatment of leptospirosis leaves much to be desired. A very limited number of patients appear to have improved to some extent after treatment with penicillin, chlortetracycline, or oxytetracycline. The authors conclude that, if any advancement in the clinical management of this disease is to be made, early and accurate diagnosis must be accomplished.

Leptospiral Meningitis. R. S. Diaz-Rivera, F. Ramos-Morales, A. F. Benenson and others. A. M. A. Arch. Int. Med. 103:886-896 (June) 1959 [Chicago].

The authors present the most salient clinical features of leptospiral meningitis observed in 29 men and 11 women, their ages ranging from 7 to 58 years, who were indigents of the San Juan metropolitan area. The patients lived in areas where rats abounded and where water pollution by the excrements of these rodents was possible. The incubation period varied from 7 to 14 days. The onset of the disease was acute and explosive, characterized by chills of variable intensity, a rapidly rising fever with prostration, severe general malaise, intense headache, and muscle aches and pains. Nausea and vomiting were recorded in most instances. Burning of the eyes with photophobia and slight lacrimation was a predominant symptom. A variable limitation of urinary output was frequently observed. Pharyngitis was observed among those who had nausea and vomiting. Hematemesis, leading to shock and death on the 8th day of illness, was observed once. Jaundice appeared during the first week of illness in 20 patients with maximum serum bilirubin values of 2 to 41 mg., and it subsided within 4 to 50 days. Of the 20 patients with jaundice, 13 presented central nervous system manifestations, and of the 20 patients without jaundice, 8 had central nervous system manifestations.

The pathogenesis of the central nervous system manifestations may be governed by various factors, including the diffuse or focal pathological alterations attributed to the direct or indirect effect of the Leptospira organisms: diffuse vascular damage, disturbances in electrolyte balance, intense hepatic alterations, or renal failure. Spinal fluid alterations are of no apparent prognostic value. In some instances the meningeal manifestations may appear as the most dominant feature of the disease, either prior to the onset of jaundice or among the patients without jaundice. These phenomena call for a refined diagnostic accuracy and an increased level of suspicion of the disease. The examination of the spinal fluid in the light of the clinical picture may aid in the establishment of the diagnosis of the disease through isolation of the Leptospira organisms. However, a bilirubin-tinged spinal fluid is of limited diagnostic value, since a clear fluid is the rule even in the presence of high serum bilirubin levels.

The pathogenesis of xanthochromia of the spinal fluid in classical Weil's disease remains unexplained. It may be governed by an increased capillary and meningeal permeability from either the direct effect of the Leptospira organisms or the complicating renal failure. It is emphasized that the anicteric form of leptospirosis [illegible] at times indistinguishable from other acute infectious diseases, mainly severe influenza without prominent signs of an acute respiratory infection. Since most of these may be accompanied by symptoms suggesting either meningitis or encephalitis, the final diagnosis must depend on laboratory confirmation. The evaluation of the extent of the cerebral and meningeal involvement in leptospirosis properly belongs to the pathologist.

Intracranial Aneurysms: Methods of Treatment: Value of Hypothermia in the Surgical Approach. E. Alexander Jr., C. H. Davis and N. C. Kester. A. M. A. Arch. Neurol. & Psychiat. 81:684-692 (June) 1959 [Chicago].

The authors report on various methods of treatment used over the past 9 years in 115 patients with intracranial aneurysms in the section of neurosurgery, Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, N. C. The management of these patients is divided into 5 categories: surgery; cervical carotid ligation; intracranial surgery without hypotension or hypothermia; intracranial surgery with systemic hypotension; and intracranial surgery with hypothermia. The evaluation of the mortality for each method reaffirmed the important value of the patient's pretreatment status. Several patients of each group who died were in such critical condition before the treatment that probably they would not have done well with any treatment. Elimination of those patients yields a comparison of mortality rates of the various treatments as follows: 44% of the patients died who were not subjected to surgery; 25% died after unmodified intracranial surgery; 43% died after intracranial surgery with hypotension; and 11% died after intracranial surgery with hypothermia. Among the patients who were not operated on, only those in good or fairly good condition on admission made an excellent or a good recovery. Among the patients who were treated surgically, however, there were several—especially in the group treated under hypothermia—who were in poor or fair preoperative condition, who made an excellent or good recovery.

The choice of operative procedure for patients to be treated by surgery seems to lie between cervical ligation of the carotid artery and intracranial approach under hypothermia. The mortality of cervical ligation of the carotid artery is relatively low, and many excellent results can be obtained by this method. This procedure does not obliterate the aneurysm and, therefore, has the disadvantage of leaving the patient liable to a recurrent rupture at a later date. In patients with very large aneurysms, or in whom anesthesia and hypothermia are contraindicated, carotid ligation may be the method of choice. The mortality of direct approach under hypothermia can be kept as low as, or lower than, that of carotid artery ligation. In such circumstances the complete obliteration of the aneurysm is a real advantage. Familiarity with this technique will give the surgeon a facility in the management of intracranial aneurysms, which will produce results superior to those of any other method now available.

PEDIATRICS

Fatal Cardiovascular Collapse of Infants Receiving Large Amounts of Chloramphenicol. J. M. Sutherland. A. M. A. J. Dis. Child. 97:761-767 (June) 1959 [Chicago].

The author reports on 3 newborn infants, 2 boys and 1 girl, who died between the 5th and 7th days of age of peripheral vascular collapse occurring after the administration of large doses of chloramphenicol which was given intramuscularly to 2 of the infants and orally to the 3rd one. Of the 3 deaths, one occurred after the administration of 220 mg. of chloramphenicol per kilogram of body weight per day for 60 hours; one death occurred after the administration of 230 mg. per kilogram per day for 72 hours; and one death occurred after the administration of 50 mg. per kilogram per day for 56 hours and 10 hours after a single inadvertent oral dose of 400 mg. The doses of chloramphenicol given to these infants were significantly larger than those usually administered. The absence of autopsy findings indicating any but minimal or subsiding infection in these 3 infants increases the likelihood that their deaths resulted from adverse drug action, although a clinical picture of vasomotor collapse and hypothermia may be associated terminally with overwhelming infections in the newborn infant.

The adverse effect of doses of chloramphenicol of one and a half recommended amounts might result from any one or more of the following factors, some of which have been suggested previously: (1) rapid destruction of bacteria and release of endotoxin; (2) drug hypersensitivity; (3) methemoglobin production; (4) overgrowth of resistant organisms; (5) toxic alternate metabolites; (6) efficient absorption and/or poor elimination of drug; (7) hypoglycemia; (8) disturbed carbohydrate utilization; and (9) adverse effect on autonomic nervous system. The observations in the 3 patients do not make it possible to ascribe an adverse effect to the drug in recommended amounts. The 3 deaths are reported in the hope of stimulating publication of the observations by other workers, which may lead to less tentative conclusions than are possible on the basis of a few uncontrolled case reports.

Congenital Asymmetry, Short Stature, and Elevated Urinary Gonadotropin. H. K. Silver. A. M. A. J. Dis. Child 97:768-773 (June) 1959 [Chicago].

The author reports 2 cases of the syndrome of congenital hemihypertrophy, shortness of stature, and elevated levels of urinary gonadotropins in a 8½-year-old Negro boy and a 6-month-old white boy. Three similar cases had been previously reported by the author in cooperation with other workers, and an abstract of the report on 2 of these cases had appeared in THE JOURNAL (154:367 [Jan. 23] 1954). The Negro boy had asymmetry of the spine, shortness of stature, an abnormally small birth weight despite a history of having been born at full term (the pregnancy, however, being complicated by the removal of a 3-lb. "fibroid of the ovary" during the 4th month), delayed epiphysial maturation, incurved little fingers, and elevated gonadotropins for the patient's age. The white boy had shortness of stature, a difference in size of the 2 legs, a drawing down of the corners of the mouth, a small birth weight despite a history of being born 2 weeks after the expected day of delivery, a single café-au-lait spot, nonpitting swelling of the dorsa of both hands and feet, incurving of the 5th fingers, moderate cubitus valgus, a slight increase in the amount of skin on the back of the neck, and cryptorchidism.

A review of these 2 cases and of the 3 previously reported revealed that the urinary gonadotropin levels were elevated for the age in all 4 patients in whom this test could be performed, being positive at 4.5, 5.0, 5.0, and 35.2 mouse [uterine] units (M. U.) respectively. All normal children who have been tested have been found to excrete less than 2 M. U. per 24 hours. No correlation seemed to exist between the syndrome as seen in these 5 patients and any of the following factors: sex, race, family history, mental development, dentition, or genital development. The structure of the skeleton was normal on roentgenograms obtained from all the patients. The author suggests that the pathogenesis of the condition described may be similar to that which occurs in patients with gonadal dysgenesis. In the 6-month-old boy, the findings of slight webbing of the neck, moderate cubitus valgus, swelling of the dorsa of the hands and feet, and wide spacing of the nipples were all suggestive of gonadal dysgenesis. However, exploratory laparotomy was not performed, and assay of urine for gonadotropins could not be carried out.

Pseudohypo-Adrenalocorticism: Renal Sodium Loss, Hyponatremia, and Hyperkalemia Due to a Renal Tubular Insensitivity to Mineralocorticoids. G. N. Donnell, N. Litman and M. Roldan. A. M. A. J. Dis. Child. 97:813-828 (June) 1959 [Chicago].

The authors report on a 7-month-old boy who was admitted to the Childrens Hospital of Los Angeles for complaints of failure to thrive and chronic eczema. Chronic dehydration, hyperpotassemia, hyponatremia, and pronounced somatic retardation suggested adrenal insufficiency. Paradoxically, the circulatory 17-hydroxycorticosteroid values were normal, and stimulation with corticotropin (ACTH) caused a normal response. The second and third hospitalizations, at 11½ and 23 months of age, lasted 9 and 2 months, respectively, and studies carried out during these hospital stays revealed that a salt-losing renal tubular defect was responsible for the patient's symptoms and that the defect was manifested by a renal refractoriness to aldosterone. The concept of renal tubular insensitivity to mineralocorticoids was further strengthened by the demonstration of the inability to induce sodium conservation by the administration of desoxycorticosterone acetate, fludrocortisone, and 2-methyl-9-alpha-fluorohydrocortisone. Initially, large loads of salt were required to correct the serum electrolytes. Subsequently the child was able to maintain electrolyte balance on standard diet, but could not tolerate salt deprivation.

Intralobar Bronchopulmonary Sequestration in Children: Diagnosis by Intrathoracic Aortography. A. P. Simopoulos, D. J. Rosenblum, H. Mazumdar and B. Kiely. A. M. A. J. Dis. Child. 97:796-804 (June) 1959 [Chicago].

The authors report on a 6-year-old girl and a 6-year-old boy with intralobar bronchopulmonary sequestration, a congenital pulmonary disease in which a portion of an otherwise normal lobe has no connection with the bronchial tree or pulmonary arterial circulation, and receives its arterial supply from anomalous branches of the aorta. Both patients had been admitted to hospitals for recurrent infection. A chest roentgenogram of the girl showed a large area of consolidation in the left lower lobe which appeared rounded in the posteroanterior view, but the borders of which were not well defined in the lateral view. A chest roentgenogram of the boy showed in the region of the left lower lobe an infiltration and multiple cystic areas, some of which had air fluid levels within them. Bronchograms in both patients revealed displacement of the bronchi and failure to fill any bronchi in the region of sequestration.

Intrathoracic aortography was performed in both patients with the aid of local anesthesia and with the use of from 0.67 to 0.75 cc. per kilogram of 70% sodium acetrizoate as contrast medium. A tortuous vessel arising from the lower part of the thoracic aorta and entering a cystic area in the left lower lobe was shown in the girl. A large anomalous vessel arising from the lower portion of the thoracic aorta and entering the area of sequestration was revealed in the boy. Resection of the posterior basal segment was performed in both patients. The postoperative course of the girl was complicated by hydropneumothorax or hemopneumothorax, which resorbed spontaneously, and the patient was discharged on the 24th postoperative day. The postoperative course of the boy was satisfactory, and he was discharged on the 15th postoperative day.

Intralobar bronchopulmonary sequestration causes chronic and recurrent infection and requires surgical removal. The condition can be identified by the history and appearance of the lung on plain chest roentgenograms and by bronchograms or by the aortographic demonstration of the abnormal systemic artery which supplies it. Pediatricians should consider this diagnosis in patients with localized chronic or recurrent pulmonary disease.

Poliomyelitis Under One Year of Age: Clinical and Laboratory Findings in a Group of 529 Patients with Poliomyelitis Younger than One Year of Age. D. Levy and W. Falk. A. M. A. J. Dis. Child. 97:829-838 (June) 1959 [Chicago].

The authors report on 529 infants, aged less than one year, with poliomyelitis who were treated at the Rambam Government Hospital in Haifa during the first 7 years of a poliomyelitis epidemic in Israel (1950-1956). Of the 529 infants, 25 (4.7%) were less than 3 months old, 108 (20.4%) were between the ages of 3 and 6 months, and 396 (74.9%) were older than 6 months. The clinical and laboratory findings in this group of patients are described. The appearance of muscular weakness, signs of bulbar or cranial nerve involvement, or encephalopathy during the first 3 days of illness were twice as frequent among patients with facial, encephalitic, or bulbar type of poliomyelitis as among patients with spinal nerve involvement. Whereas this may be a consequence of higher vulnerability of cerebellar and medullary nerve tissue during this period of life, it must be borne in mind that signs of involvement of these centers are much more noticeable than weakness of limb or body muscle in an infant. Definite signs of meningeal irritation were elicited on the lips and mouth in order to prevent accidents of invagination and possible malignant degeneration by constant surveillance and preventive operations as indicated; (2) a careful examination of the mouth in patients with an acute abdominal disturbance, because it may lead to an accurate etiological diagnosis of intestinal occlusion, which, in the Peutz syndrome, is always due to polypoid invagination; and (3) restraint in giving a patient with the Peutz syndrome too somber a prognosis, even though the histological structure of the tumors suggests cancer.

OTOLARYNGOLOGY

Bronchoscopy Under General Anesthesia in Children Aged 4 to 11 Years: Study of 422 Endobronchial Explorations Carried out by This Method in a Specialized Preventorium. G. Jamet, J. Moraine, A. Gladu and H. Petithomme. Rev. tuberc., Paris 23:231-247 (Feb.-March) 1959 (In French) [Paris].

The difficulties accompanying bronchoscopy in children, aged 4 to 11 years, led the authors to abandon the use of local anesthesia for this procedure in children of this age-group and to replace it with general anesthesia. The intravenous route is used exclusively, because inhalation methods of anesthesia proved unsatisfactory and ill-adapted to a procedure of this type. The anesthetist should confine himself to supplying oxygen alone by the aerial route. The duration of bronchoscopy is extremely variable (from 8 to 35 minutes in the authors' series); consequently, it is important to have anesthesia that can be managed easily, i. e., capable of being prolonged as needed but immediately reversible when the examination is finished. A thiobarbiturate (Nesdonal) is used for induction, while the rest of the anesthesia is secured by a curarizing drug, succinylcholine iodide, which is given in an extemporaneous solution of 10 mg. per milliliter. The doses vary with the weight of the subject. Additional injections can be given, if needed, at constantly increasing intervals in smaller and smaller doses.

No serious accident has occurred in any of the 451 bronchoscopies carried out under general anesthesia by the authors, 422 of which were in the children in this series; the few incidents noted were all minor in character and were far outweighed by the advantages of the procedure. General anesthesia enables the bronchoscopist not only to make as detailed and thorough a study of the patients' endobronchial condition in children, aged 4 to 11, as in adolescents and adults, but also to apply direct therapeutic treatment to the lymph-node lesions of a primary infection and so to provoke their involution. The presence of foreign bodies in the bronchi, quite apart from tuberculous infection, is a formal indication for bronchoscopy under general anesthesia in children of this age-group.

A somewhat more complicated bronchoscopic table is required when the examination is performed with the patient under general anesthesia than when it is carried out under local anesthesia only. The number of medical assistants must also be larger, and both the bronchoscopist and the anesthetist must be specially qualified. The anesthetist should, if possible, be experienced in giving an anesthetic for thoracic surgery and should have had practice in the use of curare. Perfect teamwork is required, so that the procedure can only be used in specialized services with experienced workers. The anesthetist should take advantage of the time spent by the bronchoscopist in cleaning and changing lenses, for example, to assure the oxygenation of the patient, and, if the procedure is prolonged, he should request an opportunity to oxygenate the patient as needed. Finally, the tube should not be withdrawn until the child has shown definite signs of waking. Bronchoscopy under general anesthesia with a combination of Nesdonal and curare has proved entirely harmless when these conditions are observed.

Malignant Tumors in Middle Ear and Mastoid Process. H. Sørensen. Ugesk. læger 121:785-789 (May 14) 1959 (In Danish) [Copenhagen].

Cancer in the middle ear and mastoid process is a grave but not hopeless disease, provided that the diagnosis is made before the tumor has reached too great an extent. From 1939 to 1953, 13 patients (7 men, 6 women), aged from 33 to 75 years, were admitted to the Radium Station and the Municipal Hospital in Aarhus, Denmark, under the diagnosis of cancer of the middle ear and/or mastoid process. In 11 cases the cancer developed during a chronic otitis; only 2 patients had not previously had discharge from the ears. In 7 cases the discharge was bloody. The frequent occurrence of chronic otitis in the patients supports the conception of the etiological significance of long-continued suppuration and stresses the importance of careful observation of patients with this disease. Cancer of the middle ear metastasizes late. The results of treatment show radical excision combined with radiotherapy to be a valuable means of treatment. In cases in which full recovery has not been attained, the patients' suffering has been relieved by a not especially mutilating intervention. Twelve patients were treated. The histological diagnosis was spinocellular carcinoma in 9 cases, basocellular carcinoma in 2, and sarcoma in 1. Five patients have been free from recurrence for more than 5 years; 1 patient died without sign of recurrence after 2½ years; 6 patients died of recurrence of the tumor.

forms, later closing of the anlage and atrophy of the muscles favor the development of the anomaly on the left, just as they do that of hernia. Acquired eventration due to phrenic paralysis is also found more often on the left side than on the right, because the liver serves as a solid barrier that interferes with the twofold factor of abdominal thrust and thoracic aspiration.

The clinical picture is variable, depending, as it does, on the effect of the eventration on the lungs, heart, and digestive apparatus. Three clinical forms may be found in children: early, in which the symptoms are apparent at or within a few hours after birth; patent, in which they usually appear between the ages of 6 and 11 years; and latent, in which obvious symptoms are lacking and the children have no more than a special susceptibility to common respiratory infections and a moderate degree of debility. Immediate surgical treatment is usually required to prevent a fatal outcome in the early forms in which cyanosis, accompanied by dyspnea or polypnea, is the dominant symptom; the few infants who survive without operation are subject to more or less severe digestive disturbances. An attitude of prudent watchfulness, on the other hand, may be maintained in the early forms characterized only by slight polypnea or mild digestive disturbances that do not interfere with the infant's growth, because they are generally well tolerated.

The symptoms of the patent forms, consisting of pain in the epigastrium or left hypochondrium, often occurring after eating and relieved by vomiting, usually interfere with normal living and affect the patient's general condition or gastrointestinal status to such an extent that operation is advisable. A latent eventration, however, which is discovered by accident in a child who is in perfect health or who has only a few discrete symptoms not affecting his general condition, should not be taken as justification for an operation.

The various methods by which diaphragmatic eventration can be surgically corrected are discussed in the light of published opinions and the authors' own experience. Three of their patients were successfully operated on; one was lost to follow-up before treatment was decided on; and in the remaining 6, in whom the eventration was more or less well tolerated, operation was not advised.

Visceral Polyposis and Cutaneomucosal Melanin Pigmentation (Peutz Syndrome). A. Mégevand. Arch. franç. pédiat. 16:353-361 (no. 3) 1959 (In French) [Paris].

Diffuse intestinal polyposis, predominating in the small intestine but occasionally extending to the stomach and the large intestine as far as the rectum, and an abnormal melanin pigmentation of the lips and labial mucosa, often accompanied by freckles, are always associated in the Peutz syndrome. All these characteristic aspects of the syndrome were present in the case of a 9-year-old boy reported on by the author. His first attack of violent abdominal pain, followed by bilious vomiting, occurred when he was 8½ years old. His history up to that time had been fairly normal in pattern, the only notable illnesses having been mumps at the age of 4 years and chickenpox and measles at the age of 8. The physician consulted during the initial abdominal disturbance, which lasted 5 days, spoke of an acetone crisis and anemia. Treatment to correct the anemia was started several weeks later at a clinic to which the child, now fully recovered from the abdominal disturbance, had been brought. An appendectomy was considered but decided against as untimely.

The following year was uneventful. The child, cured of his anemia, was perfectly well until December, when he had a sudden short attack of abdominal pain with one episode of vomiting. One week later, severe pain necessitating hospitalization recurred. A diagnosis of intestinal obstruction was made and confirmed at operation, during which a double jejunojejunal invagination was found. Two tumors, about 70 cm. apart, in the lumen of the small intestine formed the starting point of this invagination, making it necessary to remove about 105 cm. of the intestine. The postoperative period was uneventful, and in about 3 weeks anemia, which had recurred, disappeared spontaneously. Several subsequent follow-ups showed the boy to be in perfect health; he was well developed and not anemic, but the freckles and melanin pigmentation of his lips and buccal mucosa, which his mother said had first appeared at the age of 2 or 3 years, were more pronounced than they had been at the time of the first preoperative examination.

Investigation of the patient's family brought several interesting facts to light. 1. His mother had the same type of pigmentation on the labial mucosa, and she had twice been operated on, once for invagination of the small intestine and once for multiple polyposis of the small intestine, believed at the time to be cancerous. She recovered rapidly after the second operation and has since enjoyed perfect health. 2. A maternal aunt was operated on for nasal polyps at the age of 20 years, but was said not to have the characteristic pigmentation. 3. The patient's maternal grandfather had died of gastric carcinoma, but whether the tumor was a polyp that had undergone malignant degeneration is not known. 4. One uncle had had a kidney operation and was said to have had freckles; another uncle had very many freckles but no melanin spots.

Awareness of this syndrome should lead to (1) a systematic search for intestinal polyps in a child or an adult with the characteristic pigmented spots on the lips and mouth in order to prevent accidents of invagination and possible malignant degeneration by constant surveillance and preventive operations as indicated; (2) a careful examination of the mouth in patients with an acute abdominal disturbance, because it may lead to an accurate etiological diagnosis of intestinal occlusion, which, in the Peutz syndrome, is always due to polypoid invagination; and (3) restraint in giving a patient with the Peutz syndrome too somber a prognosis, even though the histological structure of the tumors suggests cancer.

OTOLARYNGOLOGY

Bronchoscopy Under General Anesthesia in Children Aged 4 to 11 Years: Study of 422 Endobronchial Explorations Carried out by This Method in a Specialized Preventorium. G. Jamet, J. Moraine, A. Gladu and H. Petithomme. Rev. tuberc., Paris 23:231-247 (Feb.-March) 1959 (In French) [Paris].

The difficulties accompanying bronchoscopy in children, aged 4 to 11 years, led the authors to abandon the use of local anesthesia for this procedure in children of this age-group and to replace it with general anesthesia. The intravenous route is used exclusively, because inhalation methods of anesthesia proved unsatisfactory and ill-adapted to a procedure of this type. The anesthetist should confine himself to supplying oxygen alone by the aerial route. The duration of bronchoscopy is extremely variable (from 8 to 35 minutes in the authors' series); consequently, it is important to have anesthesia that can be managed easily, i. e., capable of being prolonged as needed but immediately reversible when the examination is finished. A thiobarbiturate (Nesdonal) is used for induction, while the rest of the anesthesia is secured by a curarizing drug, succinylcholine iodide, which is given in an extemporaneous solution of 10 mg. per milliliter. The doses vary with the weight of the subject. Additional injections can be given, if needed, at constantly increasing intervals in smaller and smaller doses.

No serious accident has occurred in any of the 451 bronchoscopies carried out under general anesthesia by the authors, 422 of which were in the children in this series; the few incidents noted were all minor in character and were far outweighed by the advantages of the procedure. General anesthesia enables the bronchoscopist not only to make as detailed and thorough a study of the patients' endobronchial condition in children, aged 4 to 11, as in adolescents and adults, but also to apply direct therapeutic treatment to the lymph-node lesions of a primary infection and so to provoke their involution. The presence of foreign bodies in the bronchi, quite apart from tuberculous infection, is a formal indication for bronchoscopy under general anesthesia in children of this age-group.

A somewhat more complicated bronchoscopic table is required when the examination is performed with the patient under general anesthesia than when it is carried out under local anesthesia only. The number of medical assistants must also be larger, and both the bronchoscopist and the anesthetist must be specially qualified. The anesthetist should, if possible, be experienced in giving an anesthetic for thoracic surgery and should have had practice in the use of curare. Perfect teamwork is required, so that the procedure can only be used in specialized services with experienced workers. The anesthetist should take advantage of the time spent by the bronchoscopist in cleaning and changing lenses, for example, to assure the oxygenation of the patient, and, if the procedure is prolonged, he should request an opportunity to oxygenate the patient as needed. Finally, the tube should not be withdrawn until the child has shown definite signs of waking. Bronchoscopy under general anesthesia with a combination of Nesdonal and curare has proved entirely harmless when these conditions are observed.

Malignant Tumors in Middle Ear and Mastoid Process. H. Sørensen. Ugesk. læger 121:785-789 (May 14) 1959 (In Danish) [Copenhagen].

Cancer in the middle ear and mastoid process is a grave but not hopeless disease, provided that the diagnosis is made before the tumor has reached too great an extent. From 1939 to 1953, 13 patients (7 men, 6 women), aged from 33 to 75 years, were admitted to the Radium Station and the Municipal Hospital in Aarhus, Denmark, under the diagnosis of cancer of the middle ear and/or mastoid process. In 11 cases the cancer developed during a chronic otitis; only 2 patients had not previously had discharge from the ears. In 7 cases the discharge was bloody. The frequent occurrence of chronic otitis in the patients supports the conception of the etiological significance of long-continued suppuration and stresses the importance of careful observation of patients with this disease. Cancer of the middle ear metastasizes late. The results of treatment show radical excision combined with radiotherapy to be a valuable means of treatment. In cases in which full recovery has not been attained, the patients' suffering has been relieved by a not especially mutilating intervention. Twelve patients were treated. The histological diagnosis was spinocellular carcinoma in 9 cases, basocellular carcinoma in 2, and sarcoma in 1. Five patients have been free from recurrence for more than 5 years; 1 patient died without sign of recurrence after 2½ years; 6 patients died of recurrence of the tumor.

INDUSTRIAL MEDICINE

Cancer of the Scrotum in Wax Pressmen: I. Epidemiology. N. V. Hendricks, C. M. Berry, J. G. Lione and J. J. Thorpe. A. M. A. Arch. Indust. Health 19:524-529 (May) 1959 [Chicago].

This study was initiated in 1947 by a review of all cancer cases from a refinery where petroleum wax was manufactured. A detailed study was carried out of scrotal cancer by means of epidemiologic and statistical procedures. Since the time-exposure relation in occupational cancer appeared to be a factor of great importance, the study included available records for the previous 10 years and was continued for an additional 10 years, giving experience over a 20-year period. Cancer incidence figures for the refinery, as a whole, were comparable to similar figures for the general male population. The incidence of cancer among workers engaged in wax manufacture (exclusive of pressmen with 10 years' or more service) was not materially different from that among the general male population. However, the incidence of scrotal cancer among wax pressmen with 10 years' or more service was many times that of the general male population and without question is statistically significant.

Wax manufacturing methods are described, and the type of exposure experienced by a wax pressman is explained. In leaning across the side rail of the presses to clean the plates, the worker's clothing became contaminated with "slack" wax. It was the practice to tie burlap bags around the waist as protective aprons. These soon became saturated with wax and aromatic oil. Since these aprons and clothing were changed infrequently, exposure was prolonged. In the absence of frequent and adequate bathing, the exposure was, in effect, continuous. The analysis of scrotal cancer experience among wax pressmen left no doubt that these lesions were directly associated with the extensive, continuous, and prolonged exposure to "slack" or crude wax by these persons over a period of years. Such exposures could have been minimized or prevented by frequent bathing and the wearing of clean work clothing, practices which were instituted subsequently. Furthermore, a newer wax manufacturing process essentially eliminates exposure on the part of workers, with the exception of occasional mechanical workers.

Cancer of the Scrotum in Wax Pressmen: II. Clinical Observations. J. G. Lione and J. S. Denholm. A. M. A. Arch. Indust. Health 19:530-539 (May) 1959 [Chicago].

In this paper the authors describe 10 cases of squamous-cell carcinoma of the scrotum in petroleum-wax-press operators. The age of onset varied from 47 to 62 years, the average being 56 years. The period of potential exposure to unrefined wax varied from 14 to 37 years. The average potential exposure was approximately 23 years. No case of carcinoma of the scrotum occurred in wax pressmen with fewer than 10 years of potential exposure to crude wax. There was surprisingly little labor turnover on the presses; hence men working 40 years as pressmen were by no means a rarity.

The cancers usually began as wart-like lesions. Infiltration of the adjoining skin and/or intermittent ulceration of the original lesion over a period of a few months or years ultimately caused the patient to seek medical advice. Primary or recurrent lesions sometimes occurred many years after "cure," or after cessation of contact with the crude petroleum wax. Hence workers with a history of such contact should have careful scrotal examinations at relatively short intervals (3 months) throughout their lifetime. Inadequate or infrequent bathing plus the prolonged use of soiled clothing led to chronic and continuous exposure of the scrotal area of these workmen to the crude wax. Proper education of workmen and supervision in matters of personal hygiene as well as the use of protective clothing should be the basis of a protective program.

A Study of Absenteeism, Accidents and Sickness Payments in Problem Drinkers in One Industry. Observer and M. A. Maxwell. Quart. J. Stud. Alcohol 20:302-312 (June) 1959 [New Haven, Conn.].

This study is based upon the records of one company, which is located in the United States and has over 10,000 employees; in other respects the company must remain anonymous. The medical records of this company provided information on (1) all illness and injury absences of at least 8 days' duration; (2) all on-the-job accidents whether time was lost or not; and (3) all off-the-job accidents requiring an absence of 8 days or more. A group of 48 problem drinkers (32 men and 16 women), not representative of the prevalence of the problem in the company and including an excess of the long employed, was drawn and compared with 2 control groups of the same size. Each problem-drinker employee was matched by 2 counterparts in sex, age, length of service, job type, and ethnic background. The findings of the 2 control groups were combined and the data averaged for purposes of comparison with the problem group. The problem drinkers met one of the following criteria: (1) had been diagnosed in writing as an "alcoholic" by a doctor of medicine; (2) had voluntarily requested help for his own drinking problem; and (3) had given repeated evidence of intoxication, absence because of drinking verified by home visits, coupled with other conditions, such as financial trouble, domestic trouble, poor attendance, personality changes, and being arrested for drunkenness.

It was found that the group of problem drinkers had 2.5 times as many cases of illness-caused or injury-caused absence lasting 8 days or more as the control group, and 2.5 times as many days of absence. The cost of the sickness payments for the 32 men who were problem drinkers totaled $88,719, compared with $26,750 paid to the 32 men in the control group, a ratio of 3.3 to 1. In the case of the women, the ratio was nearly 2 to 1. The on-the-job accident rate of the problem drinkers after age 40 was almost identical with that of the controls. But before age 40, the problem drinkers experienced twice as many on-the-job accidents as the controls. It is hypothesized that the high on-the-job accident rate of early-stage problem drinkers is reduced in the later stage by the realization that a problem exists and the adoption of various protective measures. Such measures were not operative for off-the-job accidents. A total of 21 off-the-job accidents requiring an absence of 8 days or more was recorded for the problem drinkers and none at all for the controls. When on-the-job and off-the-job accidents are combined, for both the men and the women, the total number of accidents recorded for the problem drinkers was 3.6 times as large as that of the controls.

THERAPEUTICS

Nicoumalone: A New Anticoagulant. A. J. Brafield. Brit. M. J. 1:1211-1213 (May 9) 1959 [London].

The new anticoagulant, nicoumalone or acenocoumarol, was compared with 2 phenindione derivatives with regard to the constancy of the prothrombin levels obtained during the period of maintenance therapy. Acenocoumarol was used in the treatment of 269 patients, namely, in 155 patients with coronary thrombosis, 107 with venous thrombosis, and 7 with arterial occlusion. The dose of orally administered anticoagulant was controlled by "prothrombin" estimations, with the use of Quick's one-stage technique. Estimations were made 3 times a week, but when a patient's reaction to the drug was abnormal (more or less sensitive), more frequent controls were made. Results were recorded as "percentage prothrombin activity," the figures being obtained by reference to a "prothrombin" dilution curve. The maintenance dose with acenocoumarol varied slightly from case to case, but was most often in the region of 2 to 3 mg. a day, given as a single evening dose. The 2 phenindione derivatives were used in 117 and 242 patients respectively. Essentially the same estimation procedures were employed in all 3 groups of patients.

The results of the tests, which are recorded in a table and in a graph, show that the peak of incidence of tests within the range of 15 to 35% occurs among those patients receiving acenocoumarol, and the incidence of tests in the (undesirable) extreme ranges is also lowest in this group of patients. Furthermore, acenocoumarol is not cumulative and rapidly disappears from the body, being excreted unaltered in the urine. Only 2 of the patients treated with acenocoumarol experienced severe spontaneous hemorrhages. One of these patients was abnormally sensitive to the drug, and the second patient, in whom melena occurred, probably had a gastric ulcer. The results with acenocoumarol were superior to those obtained with the other 2 drugs.

Triamcinolone in the Treatment of Rheumatoid Arthritis. M. Thompson. Brit. M. J. 1:1259-1262 (May 16) 1959 [London].

The author reports on 12 women and 4 men, 15 of whom had rheumatoid arthritis and 1 had ankylosing spondylitis with predominantly peripheral arthritis, who were treated successively with prednisolone and triamcinolone, the ratio of dosage being 5 to 4 by weight. The daily maintenance dose of prednisolone ranged from 7.5 to 20 mg. The average daily maintenance dose of triamcinolone varied from 6 to 16 mg., according to the severity of the disease. The duration of treatment with triamcinolone varied from 2 to 26 weeks, and 11 of the 16 patients were then given an additional course of treatment with prednisolone, allowing a second comparison to be made. Of the 16 patients, 6 preferred triamcinolone, 5 preferred prednisolone, and 5 had no preference. These preferences were based on the patient's own assessments of pain and stiffness and, in addition, sense of well-being. Triamcinolone thus was found to be as effective as prednisolone in relieving arthritic symptoms in a dosage ratio of 4 to 5. Four additional patients, 3 women with rheumatoid arthritis and 1 man with ankylosing spondylitis and severe peripheral arthritis received treatment with triamcinolone given in doses of 4 mg. 4 times daily initially, which then were reduced to total daily doses of 12 mg.

Triamcinolone was found to be useful in patients with hypertension which had been induced or increased by previous steroid therapy. Weight loss and reduction of edema were noted when patients receiving prednisolone were transferred to triamcinolone. Gastroduodenal side-effects were more frequent and severe with triamcinolone than with prednisolone, and 2 of the total number of 20 patients in this series had hematemesis in the course of triamcinolone therapy. Subcutaneous ecchymoses and other side-effects of prednisolone were also observed with triamcinolone, but the pattern of involvement was not identical. From the results obtained in this series and in patients reported on by other workers, triamcinolone would appear to be a suitable steroid compound when steroid therapy was indicated for hypertensive patients or those in whom hypertension has developed with another steroid, for patients with edema and evidence of salt retention, and for patients in whom purpuric or ecchymotic lesions occurred during treatment with other steroids; it may also be of value for patients who have become restless or unduly euphoric during treatment with other steroids.

Beclamide in Intractable Epilepsy: A Controlled Trial. J. Wilson, J. N. Walton and D. J. Newell. Brit. M. J. 1:1275-1278 (May 16) 1959 [London].

The authors report on 13 patients, between the ages of 21 and 51 years, with uncontrolled, major or temporal lobe epilepsy in whom a statistically controlled double-blind trial of beclamide (N-benzyl-beta-chloropropionamide), a new anticonvulsant, was carried out in the epileptic clinic of the Royal Victoria Infirmary in Newcastle upon Tyne, England, in 1957. The patients were living active and useful lives despite their epileptic attacks, and all attended the clinic at monthly intervals for examination throughout the trial. For a preliminary period of 3 months the patients were observed on the anticonvulsant regimen they were already following. During each of 2 subsequent 3-monthly periods they received either unmarked beclamide tablets in doses of 1 Gm. 3 times daily or identical control tablets of lactose, in addition to the drugs they were already receiving. At the end of this 6-monthly period those patients whose attacks were still relatively uncontrolled were observed for an additional 4 to 8 weeks while receiving beclamide in doses of 4 Gm. daily in addition to their previous medication.

The results showed that beclamide given in a daily dose of 3 Gm. was significantly more efficient than the inert tablet, reducing the number of seizures to 75% of their previous frequency without any noteworthy side-effects. The lactose tablets did not have any psychological placebo effect. Little improvement was obtained by increasing the daily dosage of beclamide from 3 to 4 Gm., but this increased dose was given for a relatively short period and the evidence on this point is inconclusive. Beclamide has a significant anticonvulsant effect, but in view of the high cost of this drug it should be used only in epileptic patients who have failed to respond to other remedies. It appears that the drug may safely be given in combination with other anticonvulsants.

Antibacterial Activity of Serum of Normal Subjects After Oral Doses of Demethylchlortetracycline, Chlortetracycline and Oxytetracycline. H. A. Hirsch and M. Finland. New England J. Med. 260:1099-1104 (May 25) 1959 [Boston].

The authors mention previous studies on the new tetracycline antibiotic, demethylchlortetracycline, in comparison with other tetracyclines. In this paper they deal with comparisons of the antibacterial activity resulting in the serum of the same normal subjects after ingestion of equivalent doses of demethylchlortetracycline, oxytetracycline, and chlortetracycline. The antibiotics used in this study were provided in capsules, each of which contained 250 mg. of the respective hydrochloride. Demethylchlortetracycline was provided in 2 forms, one containing only lactose as a filler and the other having an equal amount of citric acid, which, in other studies, had been shown to enhance the serum levels of tetracycline. The chlortetracycline capsules contained only lactose, but those of oxytetracycline contained equal amounts of glucosamine hydrochloride, which has been reported to enhance the serum levels of that drug. The subjects for this study were 8 normal young men.

The results of the present study show that oral doses of demethylchlortetracycline, given to normal men, are absorbed as well as, or better than, equal doses of either chlortetracycline or oxytetracycline in combination with glucosamine. However, the new antibiotic produces much greater activity in serum than the other 2 analogues against each of the 3 test organisms used, namely, Streptococcus 98, Staphylococcus 209P, and Bacillus cereus 5, or when compared in terms of the concentration of antibiotic expressed as activity of any one of the analogues. Moreover, the activity produced by the oral doses of demethylchlortetracycline persists and can be detected in serum for 24 to 48 hours longer than after the doses of either chlortetracycline or oxytetracycline. The absorption of tetracycline is somewhat better than that of demethylchlortetracycline (as measured by the serum levels of the antibiotic ingested); however, as reported in the previous study by Kunin and Finland, the levels of antibiotic in the serum during administration of repeated oral doses are the same or higher with demethylchlortetracycline at all times after the first dose even when expressed in terms of the antibiotic ingested. In terms of antistreptococcic or antistaphylococcic activity, and in terms of concentration of antibiotic expressed as activity of the same standard, demethylchlortetracycline yielded higher activity than tetracycline at all times. The results of the present study did not show any improvement in absorption of demethylchlortetracycline given with citric acid.

The authors point out that the findings in this study, as in previous comparisons reported from this laboratory with this group of drugs, with penicillin analogues, and with the erythromycin group of antibiotics, emphasize the importance of using the same standard of reference in comparing different but related drugs. Comparisons based only on the concentrations of the antibiotics administered, although they are useful as indicating their relative absorption, distribution, and excretion, do not compare their relative antibacterial activity, which is the purpose for which they are used therapeutically. The new tetracycline antibiotic, demethylchlortetracycline, produces much higher and longer sustained levels of antibacterial activity in the serum after oral administration than either chlortetracycline or oxytetracycline.

Application of the Protein-Saving Effect of Androgenic Hormones in the Treatment of Patients Following Total Gastrectomy. Gastroenterology 36: 599-612 (May) 1959 [Baltimore].

Androgenic hormones have been known to exert a protein-building influence. An attempt was made to investigate whether improvement of the utilization of the protein ingested could contribute to the attainment or maintenance of a positive nitrogen balance in patients whose capacity for food uptake was limited. Investigations were made with the aid of balance tests in 16 agastric patients (1 woman and 15 men) who were given androgen therapy and in 18 agastric patients who were not given androgen treatment.

Protein utilization in all male postgastrectomy patients except one was found to be improved following administration of testosterone propionate. The nitrogen balance in the one female agastric patient was likewise improved as a result of treatment with testosterone propionate at lower dosage, combined with estrogen treatment. The patients treated with androgens showed a significantly more marked increase in body weight during clinical observation than the patients not treated with androgens. During after-treatment at the outpatient department by administration of a maintenance dose of testosterone phenylpropionate, body weight continued to increase in the majority of patients. Disagreeable or untoward side-effects due to androgen treatment were not seen. Pathological enhancement of the libido was found in none of these patients. Prostatic carcinoma constitutes an absolute contraindication to treatment with androgenic hormones. It is believed that the use of androgenic hormones merits a place in the treatment of completely or partially agastric patients who are in an unfavorable or moderate nutritional condition.

"Kanamycin," a New Antibiotic: Experimental Study "In Vitro." G. Andrieux, J. Monnier and R. Bourse. Presse méd. 67:718-719 (April 11) 1959 (In French) [Paris].

In vitro bacteriological studies on kanamycin have demonstrated the particularly interesting antibiotic properties of this new drug. It has essential bactericidal action which is effective in low concentrations against many bacteria, especially staphylococci and Proteus organisms. The pH of the culture medium has little effect on the activity of kanamycin. Another important point is the fact that serum has no inhibitory effect on its in vitro activity. Strains of bacteria repeatedly subjected to its action present progressive but slowly developing resistance, generally at moderate levels. This resistance to kanamycin acquired in vitro does not lead to a diminished sensitivity of the strains to certain other antibiotics. The combination of kanamycin with penicillin has a synergistic effect in vitro on the bactericidal action of certain strains. Acquired resistance to kanamycin is associated with a cross-resistance to neomycin and framycetine, and vice versa. On the other hand, if the strains which have become resistant to kanamycin show cross-resistance to streptomycin, inversely, strains that have become highly resistant to streptomycin retain their sensitivity to kanamycin practically unchanged.

Kanamycin given by the intramuscular route is rapidly absorbed; the blood levels obtained in animals show a high concentration in the first 15 minutes, which decreases gradually in the hours following. The antibiotic diffuses well, except in the muscles and in the brain. The urinary elimination is good, and the urinary concentrations are even higher than with streptomycin. Studies on the toxicity of the antibiotic in animals show frequent renal lesions, which, however, are reversible, whereas neurotoxicity seems to be milder than that characteristic of streptomycin. The first clinical results obtained in man indicate that kanamycin is a valuable antibacterial agent in certain severe infections, particularly those caused by staphylococci or other enterobacteria.

One Hundred Patients Treated with Dexamethasone: Comparison with Prednisone and 6-Methylprednisolone. A. Lichtwitz, D. Hioco and C. Greslé. Semaine hôp. Paris 35:1570-1580 (May 4) 1959 (In French) [Paris].

Study of the action of dexamethasone (16-alpha-methyl-9-alpha-fluoro-prednisolone [16 MFP]) in patients with various articular, allergic, and glandular disorders confirmed the reports of other authors who found that this new preparation was effective in small doses. Dexamethasone embodies all the modifications that are capable of increasing the anti-inflammatory effect of a corticoid, i. e., halogenation in the 9th position, dehydrogenation between the first and second positions, and methylation in the 16th position, and its index of efficacy in relation to that of the other corticoids (prednisone and 6-methylprednisolone) is about 7. The conditions treated were so diverse that the dosages and results in each group must be considered separately. Patients with diseases of the joints (39 in all), especially chronic progressive polyarthritis, were given doses ranging from 1 to 3 mg. of dexamethasone, rarely more or less. The doses needed in chronic progressive arthritis did not depend on the duration or extent of the disease or on its evolutionary capacity. They varied greatly from patient to patient, but in a large proportion of those with this condition better control of the disease was secured with doses 5 to 7 times less than those of prednisone. The action of dexamethasone in the inflammatory exacerbations of various arthroses and rheumatic fever, on the other hand, was identical with that of prednisone. One of 5 patients with gout derived some benefit from dexamethasone, but in the other 4 it was ineffective.

Smaller doses, not exceeding 1.5 mg., were usually sufficient for effective control of respiratory and cutaneous allergies, making the index of efficacy in these conditions about 8, or a little higher than it is in articular diseases. The index is still higher (10 or more) in patients with adrenal insufficiency (primary or secondary), while in those with adrenogenital syndromes it is more than 40. A few patients with miscellaneous conditions as different as scleroderma, pemphigus, hypoglycemia, asthenia, and nephrotic syndromes exhibited results which were, on the whole, similar to those obtained with the other corticoids, sometimes better, sometimes worse, but the numbers were too small for the formation of definite opinions.

The question to be considered in using a new corticoid, such as dexamethasone, is not only whether it is effective, because the results desired can usually be obtained with the older ones by increasing the dosage, but also, and even more, whether it is safe when given in effective and especially in comfortable doses. The subject of the accidents caused by dexamethasone and the other corticoids is discussed in the next article, in which an attempt has been made to evaluate the margin of safety between the optimal therapeutic dose and one that exposes the patients to the dangers of cortisonism.

***Intolerance, Incidents, and Accidents Provoked by* Dexamethasone (16 MFP).** A. Lichtwitz, D. Hioco and C. Greslé. Semaine hôp. Paris 35:1581-1593 (May 4) 1959 (In French) [Paris].

The 100 patients treated with dexamethasone, as described in the preceding article, were thoroughly investigated for evidences of cortisonism affecting the tissues, the metabolism, and certain glandular activities. Analysis of the data obtained shows that the efficacy of dexamethasone in doses below 2.5 mg. is greater than that of prednisone in doses below 20 mg. and that side-effects occur less frequently with it than with the other corticoids. The margin of safety, in other words, between its anti-inflammatory action and its other effects on the tissues, in these patients at least, was greater than that of prednisone. It seems, moreover, that not only are the tissues less vulnerable, but also the side-effects are different. The authors had already noted that, with 6-methylprednisolone and triamcortisone, the manifestations of cortisonism, though frequent, were not the same: thus, with 6-methylprednisolone, as with triamcortisone, the cardiac disturbances were rarer and the digestive disturbances different; by contrast, 6-methylprednisolone and triamcortisone frequently led to the complications of headache, visual disturbances, vertigo, and a disagreeable taste in the mouth, all of which are exceptional with prednisone. The authors emphasize the differences in the side-effects produced by prednisone, 6-methylprednisolone, triamcortisone, and dexamethasone, because on several occasions they have been able, by reducing the dosage of one of these corticoids, to suppress its untoward effects while at the same time increasing the anti-inflammatory effect by giving it in association with another or others. This ability to cumulate the anti-inflammatory effects of the various synthetic steroids by associating them, while keeping each one below the threshold of cortisonism, holds good only for intolerance and most of the incidents accompanying their use. Cushingoid manifestations and accidents properly so called (perforation, hemorrhages, decalcification) occur with all the corticoids and *to a certain extent in proportion to* the dosage used.

It was thought, some years ago, that it would be quite impossible to dissociate the anti-inflammatory properties of cortisone from its other qualities. Recent advances, however, in which the sodium retention of hydrocortisone has been almost eliminated by dehydrogenation between the first and second positions, and the importance of the modifications produced in the hormone by halogenation, methylation, and hydroxylation, when they concern the 9th, 6th, and especially the 16th positions, justify the belief that this dissociation can, after all, be accomplished. Dexamethasone represents a step in this direction, and even now many patients who *seemed to be resistant to corticotherapy can be* treated with the new corticoids, 6-methylprednisolone, triamcortisone, and especially dexamethasone, with greater comfort at a lower cost.

Tetracycline Provocation in Lupus Erythematosus. C. A. Domz, D. H. McNamara and H. F. Holzapfel. Ann. Int. Med. 50:1217-1226 (May) 1959 [Lancaster, Pa.].

A hypersensitivity reaction may be of vital importance with regard to lupus erythematosus; it may herald accelerated systemic spread in discoid lupus, or it may be the final disastrous turn in the course of a patient with systemic lupus erythematosus. The authors call attention to what may be a hitherto unappreciated provocative potential of the tetracyclines in lupus erythematosus. They present the histories of 3 patients in whom L. E. reactions occurred after the administration of tetracycline. In the first patient, systemic lupus erythematosus developed *de novo* after a hypersensitivity reaction to tetracycline. Despite her completely negative history for any other allergic reactions in the past, the tetracycline reaction did not represent an idiosyncrasy, but was a true sensitization phenomenon, since the drug had been administered without reaction 5 months earlier. This had served as the priming, or sensitizing, dose. Once the reaction occurred and active lupus erythematosus supervened, her reactivity was at such a pitch that a violent reaction developed to glutethimide, a drug of low sensitizing potential. The reactions to tetracycline began while she was taking hydrocortisone, and the reactions to glutethimide occurred while she was taking prednisone.

In the second patient tetracycline had been used to good advantage early in the course of her disease to treat respiratory infections. A later attempt to employ the drug proved disastrous, setting off a violent reaction which appeared to hasten her death. The cutaneous and systemic flare which followed tetracycline never subsided, but progressed until her death. The third patient initially demonstrated positive L. E. tests while he was taking penicillin and tetracycline simultaneously. The tests reverted to negative when the antibiotics were withdrawn, and a positive test was later provoked by each antibiotic separately while he was receiving steroids. At this stage of his illness it cannot be decided whether this patient has systemic lupus erythematosus or pulmonary fibrosis with rheumatoid arthritis. Circumvention of such reactions depends upon the physician's awareness of the sensitizing potential of the medications he employs. The occurrence of a drug reaction in any patient should be a signal to consider the possible presence of lupus erythematosus. In the patients presented, steroids provided no appreciable protection against L. E. reactions.

Treatment of Pulmonary Metastases of Certain Forms of Cancer of the Breast. J. Moreno, O. Mazzotti and J. Moreno Jr. Semana méd. 66:159-161 (Jan. 29) 1959 (In Spanish) [Buenos Aires].

Two patients, 40 and 55 years old, respectively, with cancer of the breast were observed. The younger patient had an adenocarcinoma of the right breast and metastases to the axillary and infraclavicular lymph nodes, which regressed after roentgen-ray castration and administration of roentgenotherapy up to a total dose of 2,500 r on the tumor and 2,000 r on the metastatic lymph nodes. Two years later a severe recurrence of the breast tumor occurred. The patient reported with acute dyspnea. Roentgen-ray examination of the chest showed bilateral miliary pulmonary metastases. Complete relief of the respiratory symptoms and disappearance or great diminution in the number of pulmonary metastases were obtained by administration of testosterone propionate in daily doses of 50 mg. in 2 series of 10 and 20 days with an interval of 10 days. Relief of the symptoms lasted for 2 years, after which the patient had acute toxic symptoms and died of metastases to the liver.

The older patient had a fibroadenoma of the right breast. Deep roentgenotherapy was followed by a period of 2 years of complete relief of symptoms and signs of cancer. A recurrence occurred, during which bilateral miliary pulmonary metastases appeared. The patient underwent radical mastectomy. Androgen treatment was given in accordance with the same schedule and doses given to the younger patient but in association with corticotropin (ACTH) in daily doses of 40 units for 10 consecutive days followed by the same number of days of rest. Duration of the treatment is not specified. The pulmonary metastases disappeared from both lungs, and the patient is living in a satisfactory state of health more than 2 years after starting the treatment. The results obtained in these 2 patients showed the favorable effects of androgens in patients with cancer of breast by improving the symptoms, making the pulmonary metastases disappear, and prolonging the life span of the patient.

Development of Peptic Ulcers During Treatment With Corticosteroids. P. Aagaard, M. Andreassen and T. Schiødt. Acta chir. scandinav. 116:423-428 (no. 5-6) 1958-1959 (In English) [Stockholm].

The authors report on 10 patients (7 women and 3 men), their ages ranging from 32 to 69 years, in whom ulcers developed after treatment with corticotropin (ACTH), cortisone, or related steroids. Nine of the 10 patients had rheumatoid arthritis and 1 patient had ankylosing spondylitis; for these conditions they received treatment from a few months to 7 years before the onset of dyspepsia. Most patients demonstrated symptoms for only a few months. None of the 10 patients had had dyspeptic discomforts before the institution of steroid therapy. The ulceration involved the stomach in 7 patients, the pylorus in 2, and the jejunum in 1. In 7 of the 10 patients, the radiograms of the stomach obtained in the early phase of steroid treatment showed normal conditions, but later a distinct ulcer appeared. This fact and the absence of dyspepsia before the commencement of steroid therapy suggest that an ulcer was actually produced.

Perforation occurred in 2 patients and hematemesis in 1 without preceding symptoms. In the remaining 7 patients, the ulcerations showed a more chronic course. Gastric resection was performed on all the patients except one. Billroth II operation was performed on 3 patients, and Billroth I on 6, including 4 patients in whom the procedure was combined with vagotomy. One patient showed adrenocortical insufficiency after the operation, but otherwise the postoperative course was uneventful in all the patients.

The patients were followed up for from 2 months to 5 years after the operation. Six of the 10 patients were perfectly well, 2 had mild dyspeptic reactions, and 2 were only followed up for 2 months after the operation. In 6 patients the steroid therapy was continued after the operation, and in spite of this, no dyspeptic discomfort occurred. Malignant transformation was not observed in any of these patients. Clinically, these ulcers are similar to ordinary gastric ulcers, apart from a less dramatic course during perforation. Pathoanatomically, the ulcers in these patients did not differ from ordinary chronic gastric ulcers.

PATHOLOGY

The Cytology of Salivary Glands Tumors. A. Appaix, H. Bonneau, and D. Sommer. Presse méd. 67:600-602 (March 25) 1959 (In French) [Paris].

A new procedure for the anatomico pathological diagnosis of salivary gland tumor consists of cytological study made possible by aspiration with a fine needle. This is easy to perform, is relatively painless, has no contraindication, is practicable in every type of patient including children, and generally obviates biopsy. The technique is simple. It consists of puncture by a very fine needle, of 0.2 or 0.3 mm. diameter, fixed on a 2-cc. syringe as airtight as possible. Needle and syringe are drawn up together. Their contents are quickly placed on a slide and fixed with equal parts of pure alcohol and ether. This is followed by staining according to Papanicolaou's technique or with Harris-Shorr's stain.

Abnormal cellular elements found by the authors are described and pictured. They include undifferentiated epithelial cells, which indicate a diagnosis of mixed tumors. These are very elongated fusiform cells with a basophil protoplasm arranged around the nucleus, presenting long extensions which give a peculiar and characteristic aspect, for which the term "fringed" is used, to the smear. Another abnormal element is the cylindrocubic cell whose protoplasm is uniform, without a vacuole, and hyperbasophilic, with a central hyperchromatic nucleus. In 3 observations cylindrical cells were found, which had an ordinary nucleus, abundant basophil protoplasm, and a vacuole in the nucleus. In most cases, however, differentiated and even eosinophil epidermoid elements are found. Cells with a neoplastic character are most frequently found among these elements.

Results of 24 examinations are given. These results were all verified by study of surgically removed material. The authors' diagnosis was correct in 18 cases of nondeveloping mixed tumors, salivary cysts, and epidermoid epitheliomas. There were 4 errors of minor importance. In 2 cases the diagnosis was mixed tumor when it should have been cystadenolymphoma, and in the other 2 the answer had been simple mixed tumor when the correct diagnosis should have been mixed tumor with epitheliomatous course. Several times punctures brought about a decision in cases in which it was a question of either paritod tumor or adenitis. The authors insist on collaboration between the clinician and the cytologist, the need of training in such examinations, and the value in doubtful cases of a preoperative extemporaneous biopsy.

Function and Morphology of the Kidney in the Course of *Thromboangiitis Obliterans.* B. Fida, U. Ruberti and A. Tizianello. Minerva med. 50:1031-1041 (April 11) 1959 (In Italian) [Turin, Italy].

Functional and morphologic conditions of the kidneys were investigated in 56 patients with thromboangiitis obliterans. There were pathological changes in the kidneys of 39 patients (70%), but the arterial blood pressure level was within the normal limits. Azotemia values were normal in all but 2 instances. Thirty-eight patients (68%) had normal constituents in the urine. Tests for kidney function revealed slight pathological states in patients with normal urine and more pronounced pathological states in patients with abnormal constituents in the urine. Pathognomonic vascular changes of thromboangiitis obliterans or presence of metachromasia were observed in only a few instances. The intima of certain vessels was slightly thicker in 2 patients. The correlation between the severity of the heart condition and the decrease of the blood flow in the kidneys was revealed by electrocardiographic findings in 39 patients (70%). Tubular capacity of excretion was preserved in patients with normal urine, and it was reduced by 37.6% in patients with abnormal constituents in the urine. Histological findings of biopsy specimens demonstrated that morphologic changes of the kidney had taken place in all the patients, being more pronounced in those with abnormal constituents in the urine than in those with normal urine.

This investigation revealed that the kidney was becoming gradually, though mildly, involved in the course of thromboangiitis obliterans, even in the absence of abnormal constituents in the urine. A severer involvement was observed in 2 patients. The involvement of the kidney became more pronounced in this series when abnormal constituents appeared in the urine.

RADIOLOGY

The Angiographic Study of Carotid Insufficiency and Cerebral Ischemia. M. M. Keirns and J. E. Whiteleather. Am. J. Roentgenol. 81:929-944 (June) 1959 [Springfield, Ill.].

The authors obtained 1,535 cerebral angiograms from patients with cerebrovascular disease in the department of radiology of the Baptist Memorial Hospital in Memphis, Tenn., between 1951 and 1958; the last 626 consecutive angiograms were obtained from 482 patients, in each of whom the cervical carotid artery, as well as the intracerebral vessels, was routinely visualized. Alterations of equipment, permitting visualization of the vessels of the neck on every cerebral angiogram, were initially made to provide for a better diagnosis of carotid occlusion. A study of the much broader problem of carotid stenosis was an outgrowth. Much information was obtained on carotid insufficiency and cerebral ischemia, a condition which most commonly affects the brain and is the second most common cause of death.

Stenosis of varying degree was seen in 119 of the 626 angiograms, i. e., 3 times more often than tumors, 5 times more often than aneurysms, and 15 times more frequently than arteriovenous anomaly. Carotid insufficiency is often clinically indistinguishable from tumor, intracerebral hemorrhage, cerebral embolus, or "idiopathic cerebral atrophy." The process starts surprisingly early in middle life; it was observed coincidentally in patients as young as 31 years of age and undoubtedly often exists for years before the diagnosis is made. In the early or developing stage, carotid insufficiency produces a variety of minimal symptoms, such as headache, mental disturbances, transient paresthesias, or speech disturbances, which are usually ignored or casually dismissed. Yet, even at the present status of vascular surgery, some of these patients can be successfully treated and should be so treated before complete occlusion occurs.

Surgical relief of the occlusive disease was attempted by endarterectomy on 32 carotid arteries in 28 patients, 11 of whom had complete occlusion of one side and 2 had complete bilateral occlusion, 7 had severe stenosis (60% or more) of one side, 7 had severe stenosis of one side and complete occlusion of the other side, and 1 had severe bilateral stenosis. Of the 28 patients operated on, 24 were men whose average age was 58 years, and 4 were women whose average age was 62 years. Of the 19 carotid arteries with complete occlusions, patency was not restored in 9; patency was restored in the absence of clinical improvement in 6; and patency was restored with a good clinical result in 4. Of the 13 carotid arteries with severe stenosis, patency was restored in 12, with good results in 5 and with excellent results in 7; patency was not restored in 1. Early surgical treatment is possible only if the disease process is suspected and the patient referred for angiography early. This should be done on patients of all types and all ages, including those who have just suffered an acute cerebrovascular accident. This policy has proved safe.

Clinical studies and especially angiography revealed 4 types of stenosing disease as follows: solitary constriction at the bifurcation of the common carotid artery; localized constriction in the carotid siphon or in the anterior or middle cerebral arteries; multiple small plaques in secondary and tertiary cerebral arterial branches; and uniformly narrow, sparse vessels throughout the brain without any definite identifiable plaques. Undoubtedly, stenosis leads to occlusion, and treatment of the stenosing plaque prevents the later occlusion. Correlation between carotid and cerebral vascular stenosis and atrophy was established.

Restoration of the Sella Turcica After Treatment of Pituitary Adenomas. S. M. Unger and B. Roswit. Am. J. Roentgenol. 81:967-971 (June) 1959 [Springfield, Ill.].

Recalcification of the eroded sella turcica, dorsum sellae, and posterior clinoid processes after irradiation and/or surgical treatment for pituitary tumors appears to be an unusual finding. Even more unusual is a reduction in the size of the enlarged pituitary fossa. Roentgenographic evidence of sellar reconstruction was noted by the authors in 3 men, between the ages of 24 and 41 years, among 70 patients treated for pituitary adenoma at the irradiation clinic of the Bronx Veterans Administration Hospital in New York. Two of these 3 patients had histologically proved chromophobe adenomas, and received surgical and irradiation therapy. In one of these 2, reduction in the anteroposterior dimensions as well as in the depth of the pituitary fossa, in addition to recalcification of the structures in the sella turcica, was revealed by the roentgenograms of the skull. A clinical diagnosis of eosinophilic adenoma was made in the 3rd patient who received irradiation therapy. A 4th patient, whose case had been reported previously and in whom such roentgenographic changes were observed after therapy, had acromegaly for which he was treated with irradiation.

A review of the literature showed that the highest incidence of restoration of the sella turcica yet reported was that of 8 among 29 patients treated for acromegalies. Other authors reported an incidence of 1 among 36 patients or 3 among 23 patients with acromegalies. Bachman and Harris pointed out that in none of their 64 patients treated for pituitary adenomas have they seen an enlarged sella turcica decrease in size or demineralized clinoid processes show evidence of recalcification. It appears, therefore, that a report of the authors' 3 patients has been well indicated.

ANESTHESIA

Pneumoencephalography and Air Embolism: Simulated Anesthetic Death. J. Jacoby, J. R. Jones, J. Ziegler and others. Anesthesiology 20:336-340 (May-June) 1959 [Philadelphia].

The authors report on 895 children and 301 adults to whom a general anesthetic was administered for pneumoencephalography performed at the Ohio State University Hospitals in Columbus between January, 1948, and January, 1958. Major complications occurred in 7 patients, causing death in 6 in the course of the procedure. Five of these deaths were in children. The diagnosis of air embolism was made and confirmed at autopsy in 4 patients; one additional patient had the clinical signs of air embolism, but autopsy permission could not be obtained. One patient died of herniation of the brain stem. The 7th patient presented another instance of brain stem herniation, in which resuscitation was successful, but the patient later died as a result of his brain lesion.

In each of the 7 patients the physiological changes resulting from air embolism or herniation of the brain stem occurred rapidly, and were manifested by abrupt embarrassment or cessation of respiration or circulation. The interpretation of these signs has been usually that an anesthetic complication, rather than a surgical, has occurred. This interpretation was not substantiated at autopsy in any of these patients. During pneumoencephalography the onset of respiratory and circulatory collapse should immediately bring to mind 2 diagnostic possibilities: after lumbar puncture, but before the injection of air, the most likely diagnosis is herniation of the brain stem; after the injection of the air, the most likely diagnosis is air embolism. Immediate recognition and prompt treatment of these complications may prevent a fatal outcome. The surgeon or anesthesiologist should listen constantly to the heart of the patient during the procedure. The beginning of a murmur is a signal to stop the injection of air. Autopsy and radiography are of value in establishing the correct diagnosis when air embolism or herniaticn of the medulla cause a simulated anesthetic death.

Clinical Trial of a New Analgesic: Dihydrone Pectinate. C. Frileux and P. Series. Presse méd. 67:729 (April 11) 1959 (In French) [Paris].

A new analgesic drug, oxycodone pectinate (French preparation known as dihydrone pectinate), has been given a 4-month clinical trial in a total of 84 patients. The drug was administered to 46 of these patients with fractures to alleviate pain, particularly that occurring after orthopedic surgery. The initial and maintenance dose varied according to the terrain (whether the patient was young and vigorous or old), and according to the intensity of pain. Generally, the dosage administered initially has not exceeded 1 ampul (24 mg.) of oxycodone pectinate given at one time, and the maintenance doses usually consisted of 12 mg. Patients who were expected to be particularly resistant were given an initial dose of 36 mg. Comparison with the effect of doses of morphine hydrochloride or pethidine usually used in similar circumstances showed that the degree of analgesia obtained by oxycodone pectinate was the same. Its effect started within 10 to 20 minutes after the injection and lasted for an average of 4 to 6 hours, which is markedly longer than the duration of the relief obtained with the other analgesics. Oxycodone pectinate offers 2 important advantages over the previously used analgesics, because it makes it possible to administer the injection at longer intervals and to give smaller daily doses with minimal side-effects.

The remaining 38 patients received intramuscular doses of 24 mg. of oxycodone pectinate combined with 0.25 or 0.50 mg. of atropine sulfate (with or without 0.05 Gm. of promethazine) for premedication prior to general anesthesia before operation. There was no respiratory depression, no postoperative change in diuresis, and no disagreeable phenomena such as are usually seen after general anesthesia. The patients belonging to the older age group received 12 mg. of oxycodone pectinate combined with 0.25 mg. of atropine sulfate, and 0.025 Gm. of promethazine. These patients remained somnolent longer and required fewer injections of postoperative analgesics at a longer interval (6 to 8 hours) after premedication. It was not necessary to give oxygen therapy after the operations in these patients despite their marked respiratory depression. The postoperative diuresis was comparable to that seen after premedication with morphine. The analgesic results obtained with oxycodone pectinate justify its use on a larger scale, particularly in older patients in whom it does not have the disadvantages of morphine.

Experience With Pharmacologically Induced Cardiac Arrest in Hypothermia. A. Martelli, E. Belelli and L. Urso. Minerva chir. 14:163-166 (Feb. 15) 1959 (In Italian) [Turin, Italy].

Studies on induced hypothermia during operation on the bloodless heart were conducted in 15 dogs. The procedure consisted in immersing the dog in an ice bath, opening the chest, clamping the venae cavae, inducing circulatory and cardiac arrest by drugs, making an incision and closing the right atrium by suture, and rewarming the animal to normal body temperature. A solution of potassium citrate was injected below the clamped sections of the venae cavae and of the aorta in 7 dogs. Irreversible ventricular fibrillation developed in all the dogs despite the cardiac massage and electric defibrillation. Intravenous injection of a dextrose solution according to the technique of Laborit, designed to prevent fibrillation from taking place when the clamps were removed, was of no avail. The heart turned flaccid and cyanotic in color, which state improved only momentarily and transitorily during massage.

A dose of 100 mg. of acetylcholine was administered to each of the remaining 8 dogs, followed by cardiac arrest which lasted up to 16 minutes. No instance of irreversible ventricular fibrillation developed in this group. Clamps were first removed from the vena cava superior and after a few seconds from the vena cava inferior when steady pulsation was established. This procedure anticipated sudden dilatation of the heart, not as yet fully tonic. A dose of 0.6 mg. of atropine sulfate was injected into the aorta before the restored circulation. Arrhythmia developed in 2 dogs when the heart beat was resumed, and it was corrected by a short massage. Electrocardiograms revealed symptoms of myocardial ischemia in those instances where prolonged asystole developed. The authors believe that acetylcholine is an efficacious drug for induced cardiac arrest and for prevention of the related ventricular fibrillation.

PUBLIC HEALTH

The Mortality from Arteriosclerotic and Hypertensive Heart Diseases in the United States: II. Possible Relation to Industry. L. H. Sigler. Am. J. Cardiol. 3:605-610 (May) 1959 [New York].

The author made a statistical study of the concentration of manufacturing establishments in the United States in relation to the mortality rates among patients who died of arteriosclerotic and hypertensive heart diseases in the United States. It was found that the mortality rates among patients who died of these diseases, as well as the concentration of manufacturing establishments, vary greatly in the different states and regions of the country. With few exceptions, a definite parallelism between the death rates and the number of manufacturing establishments in the various states was noted. Those states that have the highest concentration of manufacture generally have the highest rates of mortality due to these diseases. There is also a definite geographical distribution of both the manufacturing establishments and the rates of mortality due to these diseases, corresponding in location to the sequential expansion of settlements in the various parts of the country since colonial days. In general, those areas which were first settled and in which industry was first established have the highest concentration of manufacture and mortality rates.

One must assume that there are probably a multiplicity of factors, induced by an altered mode of living associated with modern industrial life, which predispose to earlier chronic degenerative cardiovascular diseases and death. Some of the factors may be the smog-filled, poisonous air in the industrial regions, with its gradual and continuous absorption into the circulation; confined, indoor life; insufficient fresh-air and open-air recreation; pent-up emotions, associated with monotony of automatic activity in this machine age; rapid speed of work and travel in this restless age; and extreme tensions under which men live. Confining the physician's attention only to the study of fat metabolism and dietary habits as the causes of arteriosclerotic and hypertensive heart diseases is taking too narrow a view in the investigation of the underlying causation. The study of the causation of these diseases should be broader in scope than heretofore and should include the factors listed above.

Investigation of the Source and Mode of Tuberculous Infection in Infancy. E. Bellisari and R. Gaddini de Benedetti. Arch. ital. pediat. e puericolt. 19:369-390 (no. 5) 1958 (In Italian) [Bologna, Italy].

The authors made a statistical investigation, mainly for the analysis of social factors which were related to tuberculous disease, among 224 hospitalized infants and children. The object was to contribute to a possible future public health program for the prevention of the disease. Approximately two-thirds of the patients were males. One hundred two children (45.6%) were below the age of 2 years, 79 (35.2%) were between the ages of 2 and 6, and 43 (19.2%) were above the age of 6. Varieties of the postprimary phase of the disease characterized by blood dissemination were present in 135 patients (60.7%), pulmonary postprimary varieties in 59 (26.4%), and primary varieties in 20 (8.9%), all the patients being under the age of 6 years.

Body weight was normal in about 200 (91%) of the tuberculous patients. Of 218 infants (97.7%) born at term, 193 (86%) were fed at breast for a period of over 3 months. Parents were the source of infection in 139 instances (62.5%), the mother being the source in 106 (48.8%). There was no significant difference in incidence of the disease as related to the order in which the infants were born or whether the families they came from were large or small, but the incidence was higher if the patient was the only child in a family. Since the father's occupation was known for the majority of the patients, it was manual laborer in 109 instances (66%), white collar worker in 43 (26%), and member of the professions in 5 (3.4%). The mortality rate among the patients below the age of 2 years was 17 (16.7%), and among those between the ages of 2 and 6 it was 4 (35.2%). All the patients died of tuberculous meningitis, except one whose death was from postprimary pulmonary tuberculosis.

BOOK REVIEWS

An Atlas of Normal Radiographic Anatomy. By Isadore Meschan, M.A., M.D., Professor and Director, Department of Radiology, Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, North Carolina. With assistance of R. M. F. Farrer-Meschan, M.B., B.S., M.D., Research Associate, Department of Radiology, Bowman Gray School of Medicine of Wake Forest College. Second edition. Cloth. $16. Pp. 759, with 1446 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1959.

It is difficult to review a book which provides no point for adverse criticism. The first edition of this book seemed of such excellence that one would have expected further printings rather than a new edition; moreover, it would have seemed that a second edition could add little to the completeness of the first. This is, however, far from true. The author has managed to polish and expand what was to begin with a near perfect creation. Specifically, an excellent chapter on radiation protection has been added. The sections dealing with bone growth and development, the central nervous system, the cardiovascular system, and the alimentary tract and biliary passages have been revised and enlarged. All of the illustrations are of high quality and beautifully reproduced. The line drawings are particularly notable for their clarity and concise labeling.

A prominent anatomist recently stated that he thought it was probably unreasonable to expect doctors or even senior medical students to remember any anatomy. The author, in producing this book, has entered a powerful wedge into this wall of ignorance. His interesting presentation of pertinent and clinically applicable anatomic information should have a powerful influence on changing this situation. This book can be recommended without reservation to medical students, residents in all specialties but especially radiology, and to practitioners of practically every discipline in clinical medicine who make ever increasing use of diagnostic radiology.

Inborn Errors of Metabolism. By David Yi-Yung Hsia, M.D., Associate Professor of Pediatrics, Northwestern University Medical School, Chicago. Cloth. $9.50. Pp. 358, with 127 illustrations. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1959.

It is 51 years since Sir Archibald Garrod coined the term "inborn errors of metabolism." In 1908 Sir Archibald was able to describe four inherited metabolic disorders: cystinuria, alkaptonuria, albinism, and pentosuria. Perhaps some measure of the advances that have been made in understanding the genetics and biochemistry of metabolic disorders is afforded by noting that the author is able to discuss 84 diseases under the same title in this monograph.

Progress in this area has reached the point where it has become difficult to define the borders of this field. Studies of chromosome structure and of the chemical composition of the genic material have led to the concept that all inherited characteristics must have a biochemical basis. Each gene probably represents a specific molecular configuration and must produce its effect, whether normal or abnormal, by initiating a chain of chemical reactions within the cell nucleus. In this broad view, any disease in which genetic factors are concerned could justifiably be classed as an inborn error of metabolism. The author has chosen to limit his discussion to a group of diseases in which at least a part of the chain of biochemical events leading to abnormality has been studied. The choice of conditions to be included in this category must of necessity be somewhat arbitrary. The author points up the unfinished nature of this story in a brief chapter entitled The Future of Biochemical Genetics. Here he gives a list of 67 additional diseases for which a genetic basis is well established, but the biochemical evidence is insufficient for including them in the group of metabolic errors. A second list is also given of 35 biochemical disturbances in which he considers the genetic evidence to be incomplete. It is entirely probable that both geneticists and biochemists will find that they may wish to argue with some details of this classification. Such argument would merely underscore the author's observation that this is a rapidly expanding field of knowledge in which rapid progress can be expected and which now offers a wealth of opportunity for multidisciplinary research.

The division of the 84 disease processes discussed into chapters is somewhat arbitrary. For each condition a summary is given of the clinical features, the mechanism of inheritance, the pathogenesis from the biochemical viewpoint and, usually, a brief statement on diagnosis and treatment. A few references are given at the end of each section and these are usually well chosen and include a number of summary papers that provide additional bibliographic material. Some readers may wish for more extensive documentation. The appendix represents a useful innovation. An extensive listing is given of laboratory procedures that have been used for diagnosis of the specific conditions discussed.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

For each test, a reference is given to a basic paper describing the use of the procedure in detail. The appendix gives in summary form the method to be followed, specifying reagents and similar details, and also indicates which of these procedures has proved to be satisfactory in the author's laboratory.

The author has done an excellent job of summarizing the present state of knowledge in a field that is rapidly expanding and changing. A critical reading will reveal a few statements that are open to question, and in a few instances both sides of controversial questions may not be adequately presented. Such minor defects should not be allowed to detract from the obvious merit of a book that should prove useful to both clinicians and research investigators.

Coronary Heart Disease. By John William Gofman, M.D., Ph.D., Professor of Medical Physics, Donner Laboratory, Division of Medical Physics, Department of Physics, University of California, Berkeley. Cloth. $8. Pp. 353. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1959.

This book is intended for the practicing physician and as such it must be considered a propagandistic, doctrinaire, and sophistic document. The author sets out to test those clinical measures which, in his view, have statistically supported significance in indicating future overt coronary heart disease without regard to the mechanisms involved. He proposes to use two: the diastolic blood pressure and the atherogenic index. The latter was set up by the author and his associates from the distribution of classes of lipoproteins separated by the use of the ultracentrifuge. He argues that these two indexes, when combined, predict the risk (which he carefully defines) of the future occurrence of clinical coronary heart disease. When these indexes are added year by year, their cumulative value is even better as a warning of risk than that of any single reading. He states that family background, age, sex, weight, diet, cigarette smoking, diabetes mellitus, and thyroid disease do not operate as such but determine risk primarily through their influence on the atherogenic index and the diastolic blood pressure. Occupation, stress, and physical exercise, according to the author, also operate through these two indexes, although physical activity appears to play an additional role.

His argument that the atherogenic index is better than the serum cholesterol level for practical purposes is not widely accepted and can be said to be almost uniquely identified with the author. This does not mean that the study of the various classes of lipoproteins is not a valuable research tool which has greatly advanced our knowledge. The work of many, including that of the author, has clearly proved otherwise. However, it does not follow that this makes it a better index than the blood cholesterol level, which is much simpler to determine.

It is also not generally believed that high carbohydrate diets are, under certain circumstances, highly atherogenic—a view propounded by the author. Except for the foregoing objections, the book conforms to generally accepted views on coronary heart disease. Because of these exceptions and because of bias subtly woven into the content, this volume cannot be recommended for the practitioner who has little knowledge of the recent advances in the field of atherosclerosis. However, it is recommended for the knowledgeable physician and for the student and investigator of atherosclerosis, since it gives an excellent summary of the work and views of the author. Some effort will be involved in reading the book because of the argumentative style and the extraordinary length of many paragraphs.

Diseases of the Nose, Throat, and Ear. Edited by Chevalier Jackson, M.D., Sc.D., LL.D., and Chevalier L. Jackson, M.D., M.Sc. F.A.C.S., Professor of Laryngology and Broncho-Esophagology, Temple University Medical Center, Philadelphia. With collaboration of sixty-one outstanding authorities. Second edition. Cloth. $20. Pp. 886, with 1193 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1959.

This textbook first appeared in 1945. It was intended to be "in a form most practical for those interested in these specialties, be they students, teachers, specialists or general practitioners." It was an impressive achievement, and the current editors were assisted by a large and able group of authorities. The late Dr. Chevalier Jackson is represented here by over 30 discussions in a field he largely helped to make, i. e., that of bronchology and esophagology. Those unacquainted with the history of these two areas can easily overlook the magnitude of his contribution. A large part of it is accepted by many as part of the body of general knowledge, without any thought of its originator. Dr. Jackson, almost singlehandedly, developed this art at a time when the general level of training and excellence in this specialty was not high in America. He brought it to its present state and to worldwide recognition.

It is gratifying to note that many of the original contributors are still present. Some are absent, presumably due to retirement or death, and so of necessity new faces have appeared. Some of these present new topics, such as the operation of stapes mobilization for the treatment of hearing loss due to otosclerosis. Textbooks of this type often suffer from the handicap of insufficient space. This has, in this new edition, been largely overcome by careful editing, so that it is only slightly larger than its predecessor, even though it includes consideration of all the advances of the past 15 years.

Among the truly notable discussions presented here are those on corrective plastic surgery of the nose and on functional alterations from sensory-neural lesions in the hearing apparatus. This textbook deserves the highest recommendation and should be on the shelf of each person interested in the field which it so adequately covers.

Survey of Clinical Pediatrics. By Lawrence B. Slobody, M.D., Professor of Pediatrics, New York Medical College, New York City. Third edition. Cloth. $11. Pp. 556, with illustrations. Blakiston Division, McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 36; 95 Farringdon St., London, E. C. 4, England; 253 Spadina Rd., Toronto 4, Canada, 1959.

In his preface the author states: "This survey of clinical pediatrics is not intended to replace the excellent large textbooks that are now available. It is rather designed to help the student and practitioner focus on the high lights and relationships of pediatrics." Study of the book shows that the author has done this job well in that he has taken the material of the usual textbook and boiled it down to about 20% of its original length. The volume covers the entire field of pediatrics. The presentations and discussions are brief, most of them in outline form. There are 34 tables dealing with such subjects as poisons, electrolyte solutions, formulas, exanthems, anemias, and hemorrhagic disorders. An effort has been made to present recent advances and, where there is controversy, the author has attempted to give the majority opinion. In some instances there may be some disagreement with the conclusions of the writer, but this is to be expected where some argument needs to be sacrificed to conserve space.

At the end of each chapter a group of review questions are presented. These are of an objective type. To answer them requires specific knowledge of the contents of the chapter as well as general information in pediatrics. A study of these questions is good mental exercise for anyone dealing with children and should be of particular value to persons preparing for an examination. Well-organized and well-written, this book should be of much help to the practicing physician, the intern, and the medical student who wants a survey rather than a detailed discussion of pediatric problems.

Hypertensive Disease: Diagnosis and Treatment. By Sibley W. Hoobler, M.D., Associate Professor of Internal Medicine, University of Michigan Medical School, Ann Arbor. Cloth. $7.50. Pp. 353. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1959.

This book was written to aid physicians in their treatment of hypertensive disease. The material is described under the headings secondary hypertension susceptible to cure and not susceptible to cure, primary hypertension, principles underlying treatment, and specific treatments; 12 appendixes are added. The success or failure of this volume will depend on whether it proves useful to the busy practitioner, since no attempt has been made to evaluate critically or document the evidence on which recommendations for treatment are made. The result is a highly personal book.

In general the writing is clear, if prolix, and the suggestions for treatment are for the most part adequate. The references are capriciously used and might better have been omitted. For example, the heading of appendix 7 refers to the use of chlorothiazide and ganglion-blocking agents in boldface type; just why is far from clear. Appendix 10 seriously recommends dihydrogenated ergot alkaloids as therapeutic agents worthy of two pages, while the same amount of space in another appendix covers chlorothiazide, reserpine, hydralazine, and ganglion-blocking agents. Why?

There is a need for books treating the subject of hypertensive diseases for the use of practitioners, but such books are difficult to write because they must be short, crystal clear, and exhibit the most mature judgment in the presentation of the pertinent aspects of the subject. Unfortunately this book does not live up to these requirements. The book is well made and the price reasonable.

Roxburgh's Common Skin Diseases. Revised by Peter Borrie, M.A., M.D., M.R.C.P., Physician for Diseases of Skin, St. Bartholomew's Hospital, London. Eleventh edition. Cloth. £1.17. 6d. Pp. 495, with 224 illustrations. H. K. Lewis & Co., Ltd., P. O. Box 66, 136 Gower St., London, W. C. 1, England, 1959.

The popularity of this compact volume is attested to by the fact that it is now in its 11th edition. Written as a practical book for general practitioners and students, it discusses primarily the common skin diseases from the standpoint of differential diagnosis and forms of treatment available to the general practitioner. The indications for more specialized treatments are listed and the results to be expected are outlined. The descriptions of the diseases are concise and readable, and there are useful sections on therapy which have been kept up to date. While the book is written by British dermatologists the American reader should have no difficulty with the pharmacological terminology, since only an occasional British trade name is used. Each section is illustrated with black and white clinical photographs of excellent clarity and detail. The text includes a brief index of differential diagnosis based on the morphology of the presenting lesions, which should be helpful to the student unfamiliar with dermatological nomenclature.

In this revision new paragraphs have been added on drug eruptions, nickel dermatitis, Kaposi's varicelliform eruption, Trichophyton rubrum infections, and skin planing. Major alterations have been made in the sections dealing with the general use of drugs, including steroid hormones, and in the sections on lupus erythematosus, impetigo, varicose veins, rosacea, fungous infections, tuberculosis of the skin, and dermatitis herpetiformis. The chapter on syphilis has been rewritten and reillustrated. Other illustrations have also been added. This edition should receive the same enthusiastic reception as its predecessors.

Les Cataractes congénitales: Rapport présenté à la Société française d'ophtalmologie, le 12 mai 1959. Par Jules François, professeur de clinique ophtalmologique à l'Université de Gand. Paper. 11,000 francs. Pp. 853 with 506 illustrations. Masson & Cie, 120, boulevard Saint-Germain, Paris 6e, France, 1959.

This monograph is the most recent in the annual series of reports presented to the French Ophthalmological Society. It continues the high standard of excellence established by its predecessors and is a monumental work covering all facets of congenital cataract from the embryology of the normal lens to the postoperative care of the surgically treated patient. In addition to a detailed description of the various types of congenital cataract, several chapters are devoted to general systemic diseases that are associated with it. One chapter deals with illnesses of pregnancy that have been reported to result in cataract formation in the embryo. The section on surgical treatment of congenital cataract is of particular value. One may differ with the author when he states that patients with vision of better than 0.3 (20/70) should not undergo operation since "vision of 0.4 (20/50) with accommodation is better than 0.9 (20/25) without accommodation," but one cannot argue with his plea for conservation in general. Unfortunately, in infants it is impossible to gauge accurately the visual acuity, and here clinical judgment is essential. The author believes that operation should be performed early in patients with complete cataracts to prevent the development of amblyopia. He states that the optimal age is between six months and two years. The various procedures available are well illustrated and evaluated. For the French speaking ophthalmologist this book should be of great value. It is hoped that an English translation will be forthcoming soon.

Medical Museum Technology. By J. J. Edwards, Chief Technologist, London Hospital Medical College Museum, London, M. J. Edwards. Cloth. $3.40; 21 shillings. Pp. 172, with illustrations. Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, England; 417 Fifth Ave., New York 16; Amen House, 480 University Ave., Toronto 2, Canada, 1959.

The term "medical museum technology" is defined by the authors to comprise the preservation of all forms of tissue for teaching purposes or research. The first part of the book is historical, dealing with early methods of preparation and preservation of tissues. The collections of Alexander Monro, John Hunter, Thomas Pole, and F. J. Knox are described. Many of the early medical museums dealt with natural history, medicine sometimes being incidental. With the discovery of formalin preservation, new impetus was given to the preservation of tissue. The last part of the book is devoted to detailed methods used by the authors for the preservation of specimens, including liquid mounting, color injection, the use of plastics, maceration and articulation of bones, the preparation of casts, and the making of transparencies. A final chapter deals with the organization of a modern medical museum for teaching purposes. This book should be of interest to medical historians (there are 213 references) as well as to pathologists and others working with the preservation of tissues.

Clinical Dermatology for Students and Practitioners. By Harry M. Robinson, Jr., B.S., M.D., Professor of Dermatology and Head of Division of Dermatology, University of Maryland School of Medicine, Baltimore, and Raymond C. V. Robinson, B.S., M.D., M.Sc., Associate Professor of Dermatology, University of Maryland School of Medicine. Cloth. $8.50. Pp. 242, with 117 illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2, 1959.

Years of teaching experience are reflected in this book designed for students and practitioners. The objective is achieved with a format similar to an expanded outline and with a noncontroversial approach to diagnosis of disease and treatment. Excellent illustrations and charts are distributed liberally throughout the text. Instructions and information are stated clearly and concisely. There are no references, but it is clearly implied that the book is intended to complement a larger text. The beginning consists of general background knowledge: anatomy, physiology, allergy, mycology, therapy, and related subjects. Most of the book is devoted to specific diseases discussed under regional involvement, morphologic groups, and those involving cutaneous appendages. All the information is readable and presented at the medical student's level in orderly, informative, brief, yet interesting fashion. The material is current.

Freedom from Fear. By Lester L. Coleman, M.D. [Second edition.] Cloth. $4.95. Pp. 293. Hawthorn Books, Inc., 70 Fifth Ave., New York 11; McLelland & Stewart, Ltd., 25 Hollinger Rd., Toronto 16, Canada, 1959.

The revised and expanded edition of this book continues the favorable climate of knowledgeableness that characterized the first book at the time of its publication. Since no single person is ever completely free from fear, this book serves a useful function in explaining, interpreting, and perhaps abolishing some of the common insecurities that trouble men and women in what has been called the age of atomic anxiety. As a readable work, it is highly recommended.

QUESTIONS AND ANSWERS

ESTIMATING PENICILLIN DOSAGE

To the Editor:—*What method is recommended for estimating the dosage of penicillin? Is the weight considered primarily? Is age important?*

Roy Lynde, M.D., Ellendale, N. D.

Answer.—The type of infection being treated, the kind of preparation, and the interval between injections are apt to be more important than the weight or size of the patient in determining penicillin dosage. This is particularly true since with most penicillin-susceptible infections we are apt to use overdosage because the drug is inexpensive and reactions are due to allergy rather than toxicity. Size of adults within wide limits is usually not considered, unless the adult is very large and the presence of a relatively resistant organism makes the attainment of unusually high blood levels important. Size is considered in children, particularly smaller children. The American Academy of Pediatrics recommends for intramuscular dosage of procaine penicillin G 10,000 units per pound of body weight, or 100,000 to 300,000 units per day, and for benzathine penicillin G 600,000 or 1,200,000 units in a single injection.

EMERGENCY THORACOTOMY AND CARDIAC MASSAGE

To the Editor:—*What are the indications for emergency thoracotomy and cardiac massage? The question arises because of two incidents reported in newspapers. In each, citizens of some prominence collapsed at public gatherings. Doctors were called, and in each case the presumptive diagnosis was coronary occlusion. Jackknife thoracotomies were performed, but despite cardiac massage both patients died. In your opinion, is such a gesture ever worthwhile outside a hospital? For example, if I as a radiologist encountered cardiac arrest in a patient while performing an excretory urogram in my office, could I be charged with negligence if I failed to open the patient's chest and massage his heart?*

John L. McClenahan, M.D., Philadelphia.

Answer.—It seems reasonable to state that emergency surgery for cardiac arrest should be performed only where operative facilities are available. These may be provided by a hospital, an emergency room, the surgeon's office, or a well-set-up aid station. It is unlikely that suitable facilities will be found on the golf course, at the roadside, in a banquet hall, or in public buildings. The present use of emergency penknife thoracotomies is an inevitable aftermath of lay publicity that has attended well-founded operations for cardiac emergencies. Not too many years ago, emergency tracheotomy was in vogue and occasionally was carried out by an aggressive bystander with somewhat questionable indications. This procedure is performed rarely now except in the hospital.

Treatment of unexpected cardiac arrest requires more than thoracotomy and cardiac massage. Proper oxygenation of the helpless patient must be provided, as well as other supportive measures, or the spectacular slash and the dramatic assault upon the flaccid myocardium accomplishes little. Although the number of emergency thoracotomies performed under such exotic circumstances has not been recorded, it is safe to assume that over-all results are not impressive. With sober reflection, it appears that the hysterical application of a sound principle in resuscitation may do more harm than good. It is agreed that every physician should understand the general principles of cardiac resuscitation and that the responsible physician in charge of any type of emergency situation must exercise his own best judgment. He alone must assess the emergency situation, and, if cardiac arrest has occurred, decision to operate must be based on facilities at hand and the chance for success. The diagnosis of sudden death is not in itself an indication for emergency thoracotomy.

A consultant's opinion on legal implications in this type of situation is as follows:

Answer.—The law requires that a physician who undertakes to treat a patient must possess a skill, and exercise the care commonly possessed and exercised by other reputable physicians in the locality. If he holds himself out as a specialist, he must meet the standards of a specialist in the designated field of practice. His duty is not changed even if his professional services are rendered gratuitously. It follows that no malpractice charge is justifiable unless the physician's service to the patient does not meet the requirements of good medical practice; unless, in diagnosis and treatment services, the physician fails to do something he should do, or does something he should not do in terms of accepted standards of practice.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

There is frequently a wide honest difference of opinion, and the attending physician must exercise his best judgment in deciding what to do in a given situation. A physician is justified if his conduct in a given situation would be approved by even a respectable minority of his fellow practitioners in the same locality. He may make a mistake, or be guilty of an error of judgment; he may obtain a bad result instead of a satisfactory one; but none of these is sufficient to fasten on him the charge of malpractice.

Generally, a physician has no legal obligation to treat a stranger whom he has not accepted as a patient. If an emergency occurs at a public gathering, the physician has no legal obligation to treat the victim. However, in this consultant's opinion, there is an ethical and moral obligation on the physician to render emergency treatment where the life of the victim is at stake. Once the physician undertakes to render emergency treatment, he may be held liable for possible malpractice.

If a radiologist should encounter cardiac arrest in a patient while performing an excretory urogram in his office, he should recognize that a physician-patient relationship exists. He cannot choose to ignore the patient merely because the emergency treatment is in a field other than his specialty. The radiologist should act in the same manner and conform to the same standards which are expected of reputable physicians in the community. This means that he need not open the patient's chest and massage the heart if standard medical practice in the community does not include emergency treatment of this type in a physician's office. Some physicians are excessively aware of their legal obligation to the patient and may misconstrue this. Fundamentally, the physician's legal obligation is to practice good medicine. If he does this, he usually will find that his moral and legal obligations are fulfilled.

RECURRENT ORAL ULCERS

To the Editor:—*A 23-year-old female, who has one child, has a negative history except that she has had recurrent ulcers of the mouth since she was a child. If there are several present, she may have slight fever. Her grandmother, mother, and two sisters have all had oral ulcers intermittently throughout their lives. None of the male members of the family has had such a lesion. The patient is in excellent health otherwise. The ulcers are shallow, tender, and painful. They measure from 1 or 2 mm. to 1 or 2 cm. in their greatest diameter. Please discuss diagnosis and therapy.*

Dale C. Hager, M.D., Beaumont, Texas.

Answer.—Diagnosis of recurrent aphthosis is based primarily on the appearance of the clinical lesions and the course of the disease. Exclusion of other ulcerative diseases of the mouth is important in substantiating the clinical impression. The cause of recurrent aphthous stomatitis is not known. A viral etiology has been postulated. This, however, has not been substantiated by investigative workers. Sensitivity to certain foods and drugs, as well as emotional stress, has been noted to precipitate these attacks. Chocolate, nuts, and barbiturates may produce the reaction, which is often called erythema multiforme when produced by a drug.

Other conditions which produce ulcerations of the mouth, such as syphilis, moniliasis, ulceromembranous stomatitis (Vincent's disease), and so-called electrogalvanic ulcers, must be considered in the diagnosis. These conditions ordinarily do not produce recurrent problems, however. When the ulcerative condition of the mouth is associated with ulcerations of the genital area and involvement of the eye, it is termed Behçet's triple-symptom complex. Severe aphthosis has been called periadenitis necrotica mucosa recurrens by Sutton.

Important in the care and treatment of recurrent aphthosis is maintenance of proper nutrition. Pain-relieving solutions can be used in the mouth prior to meals and a soft diet followed. A tripelennamine solution held in the mouth for 15 minutes before eating should suffice. Pyridoxine ointment and chlortetracycline mouthwash have been advocated as topical therapy. Due to the postulated viral etiology, repeated smallpox vaccinations, poliomyelitis vaccinations, and administration of gamma globulin have been advocated for prevention of further attacks. However, therapy in most cases is discouraging.

SCHOOL TUBERCULIN TESTING

To the Editor:—*In our tuberculin-testing program we have limited the testing of children to the junior class of high school. They have been tested both by the purified-protein-derivative routine and also by mass x-rays on the small film. We would like to resolve the controversy that has arisen in our school system as to the relative merits of the above procedures. Does one have any advantage over the other?*

Raymond T. Houle, M.D., East Hartford, Conn.

Answer.—At the present time it is the recommendation of leaders in the field of tuberculosis control that the tuberculin status of a child be known on his entrance into kindergarten or first grade and every four years thereafter. X-ray studies are limited to those having a positive tuberculin test. It is common practice at the present time not to x-ray high school students routinely, because of the low productivity of cases. In many areas of the country, it is recommended that a small screening chest x-ray be made once during the high school period to discover possible congenital abnormalities or any other defects which might not be found on physical examination but should be a part of a complete health record. The testing program described may be incomplete if it does not allow for testing of new admissions to the schools each year.

For tuberculin testing, use of a single intradermal dose of intermediate strength containing 0.0001 mg. of purified protein derivative (5 tuberculin units) or 0.1 mg. of old tuberculin is recommended for case-finding programs unless there is a history of tuberculosis in the family, in which case a weaker solution would be used in the original test. Once the school record reveals a postitive tuberculin test, the test is not repeated. Since the incidence of active tuberculosis in the average high-school-age population is exceedingly low in most areas of the country, the tuberculin test procedure is fairly well agreed on by school physicians as the method of choice in tuberculosis case-finding programs.

STATUS OF ELECTROMYOGRAPHY

TO THE EDITOR:—*I should like to inquire as to the status of electromyography in the diagnosis of peripheral and central nerve lesions. I am particularly interested in its effectiveness in differentiating disease of the nerve itself from external pressure such as tumors or disk abnormalities. I should appreciate information as to references on evaluation of electromyography.*

M.D., Washington.

ANSWER.—The recording of spontaneous or induced electrical activity or action potentials by means of electromyography does permit differentiation of central and peripheral nerve lesions in many instances. Neurogenic lesions that irritate or produce denervation of motor units are distinguished by the presence of fibrillation and fasciculation potentials, as well as by variations in amplitude, duration, distribution, and complexity (i. e., polyphasic forms) of the potentials. Localized lesions such as a tumor or a ruptured disk would produce segmental electromyographic abnormalities in the motor distribution of the involved roots.

BLOOD-TINGED SEMEN

TO THE EDITOR:—*A man, aged 50, about a year and a half ago noticed blood-tinged semen in the condom after intercourse. He has had recurrence since then; recently there was considerable blood. Urologic examination a year ago, including cystoscopy, was normal. What may cause such bleeding? Is specific treatment indicated?*

Jerome Kogan, M.D., Stamford, N. Y.

ANSWER.—Blood in the semen (hemospermia or hematospermia) is due almost exclusively to inflammation of the mucosa of the seminal vesicles; i. e., chronic or subacute seminal vesiculitis. It may be associated with neoplasm of the seminal vesicles, but such neoplasms are extremely rare. The condition is particularly prone to recur. As a rule, it is of no consequence. Seminal vesiculitis is most commonly caused by a low-grade hematogenous or blood-borne infection. Except in the case of obstruction of the seminal ducts, it rarely causes clinical symptoms. One can make the diagnosis by a careful rectal examination. The seminal vesicles are not indurated, but strippings in between times usually show some old oxidized blood with a considerable mixture with various types of sperm. One finds this in persons who have no evidence of focal infection. It is important to have definite proof that seminal vesiculitis is the cause of hemospermia. A satisfactory method is to have the patient come to the office with a full bladder. The prostate and seminal vesicles are stripped completely but gently rectally. Then a midstream specimen of urine is sent for laboratory culture and analysis. About 50% of these patients will show no growth from these specimens. The other 50% will show, as a rule, hemolytic or nonhemolytic coccic infection.

STERILIZATION STANDARDS

TO THE EDITOR:—*The National Presto Industries, of Eau Claire, Wis., puts out an appliance advertised as being effective as a sterilizer utilizing either dry heat, boiling, or as an autoclave, and they state it is effective against spore-bearing bacteria. Can you tell me whether it is satisfactory? Does it meet the standards of sterilization of the Pharmacopeia of the United States?*

Lester J. Candela, M.D., New York.

ANSWER.—The Pharmacopeia of the United States (15th revision, page 828) states: "The preparation of sterile products requires intimate knowledge of the equipment being used and of the stability of the product being processed. The processing requires vigilant supervision of equipment and procedures by personnel well trained in devising and applying methods for attaining sterility, and adequate proof of the effectiveness of procedures used." There is no reason to doubt that the electric unit supplied by National Presto Industries, Inc., would fulfill the requirements mentioned provided it is mechanically sound, its instrumentation accurate, and the process applied by well-trained personnel.

The manufacturer provides clear-cut directions for operating the unit, including statements of temperatures and times for sterilizing by steam under pressure, hot dry air, and boiling water (used only if techniques do not require the elimination of heat-resistant bacterial spores). Their brochures do not include microbiological data, but they may have evidence of satisfactory results with "spore strips" and similar indicators. Their recommended cycles for sterilization of syringes, needles, glass, rubber goods, instruments, utensils, dressings, and linens are stated. The size of the unit's container, diameter 8.5 in., depth 4.5 in., may limit its use in some situations. This disadvantage would appear to be offset by the claimed rapidity with which the unit reaches required temperatures.

SUSPECTED CONTAMINATION OF SOFT DRINK

To the Editor:—*A woman consumed a soft drink, obtained from a vending machine, which was said to be contaminated with insects, thought to be cockroaches. About 24 hours later, she stated that she developed nausea, vomiting, and generalized abdominal pain. There was blood in the vomitus, and she vomited several times. No diarrhea developed. Examination revealed epigastric tenderness and a temperature of 100 F (37.8 C). The patient complained of intermittent abdominal pains for several weeks. Otherwise she responded well to conservative medical measures. Could this situation have been responsible for the symptoms and findings described? What could have been the cause—bacteria, toxins, or perhaps some chemical that was absorbed? Could this clinical picture have had a functional basis? Are vending machines considered safe containers for soft drinks?* *M.D., Illinois.*

Answer.—The fact that the patient was not ill until 24 hours after taking the soft drink would exclude a psychogenic reaction from associating insects with it. Roaches in a soft drink would not per se be responsible for the symptoms and findings described. Roaches may carry microbial contaminants on their feet and spread them to foods with which they come in contact. Without stool cultures it is impossible to rule out microbial foodborne illness.

Food-poisoning strains of staphylococci produce a poison (enterotoxin) when they have suitable conditions for growth in a food. Some human volunteers fed small doses of enterotoxin vomited without having diarrhea, whereas others had diarrhea without vomiting. However, in this type of poisoning the incubation period is one to five hours after eating food containing the enterotoxin. Food items eaten subsequent to consumption of the soft drink should be considered. Much study has been made of vending machines with relation to sanitation. In general, licensing is confined to machines meeting sanitary standards.

POSSIBLE CAPILLARY FRAGILITY

To the Editor:—*In a woman, a slight blow anywhere on the body causes black and blue spots, with no tenderness. They go away in a few days. What can she take to prevent this condition?*

Stanley W. Blanchard, M.D., Boston.

Answer.—The question suggests easy bruising and increased capillary fragility, but there is inadequate information to permit any speculation as to its pathogenesis, such as possible hereditary aspects, nutritional history with special regard to ascorbic acid, hypertension, and the particular location of the ecchymoses (body or extremities). It is also important to know whether the patient is experiencing other hemorrhagic phenomena such as epistaxis, gingival bleeding, or undue bleeding after cuts or in association with her menses. Important laboratory tests are needed, including bleeding time, platelet count, and the Rumpel-Leede test for capillary fragility.

Aside from a distinct coagulation defect or thrombocytopenia, a common cause of this type of easy bruising is subclinical scurvy, an entity all too frequently unnoticed in our generally well-nourished population. For one reason or another, many persons place themselves on vitamin C–deficient diets because of the idea that the ascorbic acid–containing foods disagree with them or for some other unrelated reason. This can be readily rectified by the administration of vitamin C. No other therapeutic agent useful in combating increased capillary fragility is known, unless it be the steroids, which are reserved for clear-cut thrombocytopenic purpuric bleeding.

PULMONARY FUNCTION STUDIES

To the Editor:—*As hospital anesthesiologist, I have been receiving requests for pulmonary function studies. Can you offer suggestions as to apparatus required and its cost?*

William B. Adams, M.D., Muncie, Ind.

Answer.—Each year at the A. M. A. convention in June, a demonstration is held continuously under the direction of Dr. Meneely on pulmonary function testing. Specialists in the field give demonstrations and are available for discussion. It is recommended that you attend such a demonstration. If this is impossible, you can obtain as references "The Lung: Clinical Physiology and Pulmonary Function Tests," by Comroe and others, and "Methods in Medical Research," vol. 2, edited by Comroe, both published by the Year Book Publishers, Inc., Chicago.

The primary instrument for pulmonary function studies should be a recording spirometer with fast-speed drum and larger capacity than the usual closed-circuit basal metabolic rate machine. With such an instrument, one can become familiar with breathing patterns, vital capacity measurements, various timed vital capacity methods, and recording of maximum breathing efforts in various types of disease. After experiments with this equipment, one can judge his own need for additions of procedures and equipment in line with requirements and interests in his own area. Warren E. Collins, Inc., 555 Huntington Ave., Boston 15, makes 9-liter and 13.5-liter capacity units costing $550 and $750 respectively. If simpler and more portable apparatus is desired, the McKesson Vitalor, priced at $127, can be used for limited observations. It should be noted, however, that simple equipment is usually best used for special applications by someone already familiar with pulmonary function testing.

CONVULSIVE SEIZURES

To THE EDITOR:—*A 42-year-old male who had gone to bed suddenly had a strong urge to defecate. He remembered nothing further, but his wife stated that he shook all over and became unconscious for a few minutes. The patient recalled a similar episode about two years previously. There is a history of a skull fracture at the age of 9 without apparent residual effects. While examining the patient, I felt a mild electric shock through my fingers. He had an electric blanket over him and was naked from the waist up. This sensation left when the blanket was unplugged. The patient's only complaint was backache. His sensorium was clear, and he had not been drinking. Office examination a few days later failed to reveal any pathology. An electroencephalogram (EEG) was reported as normal. I thought he had had an epileptic seizure, but, with the normal EEG and the strange shock from his blanket, I wonder if he could have been shocked into a convulsion? Could an epileptic seizure be triggered by an electric blanket?*

John B. Umhau Jr., M.D., Chevy Chase, Md.

ANSWER:—This question was discussed with several experts in physical medicine and by a neurologist interested in convulsive seizures. The control box of the standard electric blanket contains a transformer that reduces the alternating household current from the usual 115 volts at the outlet to 18 volts at the blanket. In electroshock therapy it is necessary to apply much higher voltages, with firm electrical contacts on each side of the skull, in order to produce a convulsion, and the experts consulted do not believe the voltage from an electric blanket would produce such convulsions or trigger an epileptic seizure. About 10% of epileptics have normal EEG's at one time or another. It would be logical to ignore both the electric blanket and the EEG and to consider this to have been a convulsive seizure of the usual sort, the etiology of which is often obscure.

GRITTY SENSATION IN MOUTH

To THE EDITOR:—*A woman, 72 years of age, for the past two years has had a gritty sensation in her mouth, particularly around her lower dentures, which are the plastic type. She has worn dentures since age 45. An allergist has found no sensitivity to such dentures or other substances. She has diminution of saliva and complains of dryness in the mouth which is relieved for only a few minutes by taking food or liquids. Her general health is good except for moderate hypertension. There is no swelling or tenderness of the parotid glands, and the ducts are not palpable. I will appreciate suggestions on etiology and therapy.*

M.D., North Carolina.

ANSWER.—If these are the original dentures, undoubtedly some resorption of the alveolar ridges has occurred. This would make for improperly fitting dentures, which would cause irritation and inflammation. Also, unless scrupulous cleanliness has been observed in care of the dentures, deposits of salivary calculus may have formed on them, creating the sensation of "grittiness" of which the patient complains. A third point is that at this patient's age there undoubtedly is some atrophy of the salivary glands, with diminution in salivary flow. Decreased salivary flow is also seen as a postmenopausal symptom and in aged people, in general. The treatment should consist of new dentures, if her present ones do not fit properly; use of a mild sialagogue, such as pilocarpine hydrochloride, to promote flow of saliva; and scrupulous cleanliness in care of the dentures to avoid the deposition of salivary calculus.

USE OF FIRST-AID ANTISEPTICS

To THE EDITOR:—*Please let me know if Bactine is as effective as thimerosal tincture.*

L. G. Haupt, M.D., Chicago.

ANSWER.—Bactine contains as its active ingredients methylbenzethonium chloride, polyethylene-glycol mono-iso-octyl phenyl ether, chlorothymol, and alcohol. As such, it is known to possess antiseptic properties which may be of some value in first-aid care of minor injuries. No studies have been seen comparing the efficacy of Bactine with that of other agents commonly employed as first-aid skin antiseptics. Some authorities believe such agents are unnecessary for application to minor injuries as a first-aid measure and simply advise thorough cleansing with ordinary soap and water without the application of disinfectants. For general information on the subject of skin disinfection, see the notes that appeared in THE JOURNAL (158:619-620 [June 18] 1955; 119:759 [June 27] 1942). More comprehensive discussions will be found in standard textbooks such as those of Sollmann (Manual of Pharmacology and Its Applications to Therapeutics and Toxicology, ed. 8. Philadelphia, W. B. Saunders Company, 1957) and Goodman and Gilman (Pharmacological Basis of Therapeutics: Textbook of Pharmacology, Toxicology, and Therapeutics for Physicians and Medical Students, ed. 2, New York, the Macmillan Company, 1955).

INTERNAL MENSTRUAL TAMPONS

TO THE EDITOR:—*Some nursing schools in this locality have taught that use of internal tampons for menstrual hygiene is not wise, in that "they change the acidity of the vaginal secretions." Is there any evidence of appreciable change in vaginal secretion as a result of use of tampons or of an increase in incidence of vaginitis?*

Eugene M. Holden, M.D., Amherst, Mass.

ANSWER.—There is no proof that vaginal tampons adversely affect the vaginal acidity or secretions or increase the frequency of vaginitis. Brand (*Brit. M. J.* 1:24, 1952) studied 100 women who used vaginal tampons during 3 to 10 successive menstrual periods. Smears and cultures taken both before and after each period failed to show any appreciable change in the bacterial flora of the vagina. Likewise, there were no signs of local irritation or inflammation.

MARITAL STATISTICS

TO THE EDITOR:—*What are the statistics with regard to yearly marriages, yearly divorces (throughout the nation), the estimated number of marriages broken by desertion* (a) *through husbands leaving and* (b) *through wives leaving, the estimated numbers of marriages broken by separation* (a) *through the courts and* (b) *among Catholics, and the estimated number of children left in broken homes yearly? What are the statistics with regard to the percentage of women who are identified a "frigid" and men diagnosed as "impotent"?*

Edward Dengrove, M.D., Asbury Park, N. J.

ANSWER.—These vital statistics, of course, vary from year to year, and some are guesses at best. The National Office of Vital Statistics estimates the number of marriages in 1958 as 1,445,000. The number of divorces is close to 40,000 each year. There are no actual figures on the number of desertions and separations each year. A. C. Kinsey believed they total about the same as the number of registered divorces. The number of children affected each year by broken homes has been estimated at 150,000. Figures for frigidity and impotence are unknown and at best would depend largely on the definition of those terms; moreover, a woman may be frigid one year and not the next. At any one time, a conservative estimate would be that 25% of all wives are not sexually satisfied. The percentage of husbands who are sexually inadequate would probably be at least as large. The number of husbands who are completely "impotent" in the sense that they are unable to have sexual intercourse is very small—among men under 40 years of age, possibly not more than 1%. Among old men, on the other hand, "impotence" is naturally the rule. No figures on these questions are very meaningful unless carefully defined, and even then they are nothing but estimates based on various small samples.

PSYCHIATRIC CARE IN GENERAL HOSPITAL

TO THE EDITOR:—*A private general hospital is contemplating a 40-bed addition and is interested in making some of these beds available to psychiatric patients. At present, there are no facilities for hospitalization of psychiatric patients in this area. I would appreciate information on cost of constructing and running such a unit.*

Robert A. Richards, M.D., San Pedro, Calif.

ANSWER.—There is general acceptance of the principle that psychiatric care can be given advantageously in the community hospital. The open ward is coming more and more into favor, with two or three rooms specially furnished for the excited patient during the first two or three days of hospitalization. It is generally considered advisable to have three patients in a bedroom, where studio-type beds should be substituted for the standard hospital bed. Living quarters should be made as attractive as possible, and there should be space provided for occupational therapy, music therapy, and other activities that may be specifically suggested by the psychiatrist who will have the hospital service.

The cost of constructing such a unit compares favorably with the cost of constructing a patient floor for surgery or internal medicine. Recent figures published by the Public Health Service for Hill-Burton grant hospitals show the average cost of construction in 1958 was $19,000 per bed. The cost of operation also compares favorably with the cost of operating a general hospital. Since the patient-stay approximates 30 days as compared with 7 days for the average general hospital patient, the per diem cost is comparatively lower while the per case cost is, of course, higher.

REMOVAL OF SKIN DISCOLORATION

To the Editor:—*I will appreciate any ideas concerning eradication of skin discoloration from syphilis. I have been trying mercury ointment with very little success.*

J. E. Joice Jr., M.D., Warren, Ohio.

Answer.—It would be best perhaps to let time take its course. Mercurial ointment is frequently effective but, as in this case, not always. Ointment containing monobenzyl ether of hydroquinone has also been used with success, but warnings have been noted recently that there is a possibility that the depigmenting effect may get out of hand and the appearance of large areas of leukoderma may result.

"FIBROTIC" UTERUS AND FIBROID

To the Editor:—*Please advise how to differentiate a fibrotic uterus from a fibroid tumor. How large may a fibrotic uterus be in a patient aged 45?*

Aaron N. Gorelik, M.D., New York.

Answer.—The term "fibrotic" uterus is a misnomer. It does not represent a clinical entity. A physiological replacement of uterine muscle cells by connective tissue occurs after pregnancies, so that some small increase in uterine size can occur as the patient approaches the menopause. A fairly symmetrical enlargement of the uterus, rarely reaching the size of an orange, can occur as a result of adenomyosis. This diffuse enlargement may involve one wall or the entire uterus. The increased size of the uterus is the result of invasion of the muscle wall by endometrial tissue. The cut surface presents a whorl-like, trabeculated appearance with dark hemorrhagic or chocolate-colored areas of endometriosis. Myomas of the uterus are discrete tumors, invariably multiple, and most often in the wall of the uterine corpus. Their size and location vary widely, and their appearance may be altered by degenerative changes. Although a large tumor may symmetrically enlarge the uterus when it is located predominantly in the uterine wall, it retains its discrete character.

ROUTINE DENTAL X-RAYS

To the Editor:—*In view of the present trend away from annual routine x-ray examinations, please advise regarding recent opinions or policies in relation to the taking of routine dental x-rays once or twice a year.*

Sidney Franklin, M.D., Youngstown, Ohio.

Answer.—The practice of making routine x-ray examinations in dentistry varies. An initial, complete full-mouth x-ray examination is regarded as necessary to a proper dental diagnosis. Unless a particular disease or treatment requires otherwise, it is generally unnecessary to repeat the full-mouth examination oftener than at three-year or four-year intervals. However, it is considered good practice to make an annual x-ray examination of the teeth with use of the "bite wing" film technique, which permits x-rays of the crowns of both the upper and lower teeth on one side to be taken in a single exposure. In patients who have a high index of caries activity, it is often necessary to repeat the bite-wing x-ray examination every six months. It is of considerable advantage to detect and treat diseases of the teeth and their supporting structures at the earliest possible moment.

COLORLESS HAIR IN NEWBORN INFANT

To the Editor:—*A 33-year-old patient, gravida 2, para 1, had been taking prednisone for five years for rheumatoid arthritis. Therapy was stopped in October, 1958, when she was in the fourth month of pregnancy. She then began taking a succession of other drugs, including chloroquine; tablets of sodium salicylate, sodium* p-*aminobenzoate, and ascorbic acid; and chlorpromazine. In November, 1958, her hair began turning white at the roots and her eyebrows and eyelashes became white. This condition still persists. On March 3, 1959, she was delivered of a healthy female infant who appeared perfectly normal except that hairs in the eyebrows and eyelashes are colorless except for the ends, which are dark. Has this type of phenomenon been reported before? Will the baby continue to have colorless hair and, if so, can this be treated?*

Erie Dell Adams, M.D., Lubbock, Texas.

Answer.—Patients on chloroquine therapy have occasionally been known to have discoloration of the hair. However, on withdrawal of the drug, the pigment returns to normal. No case is known in which a healthy child born of a mother with white hair, eyebrows, and eyelashes has been born with colorless hair. The chloroquine might affect hair pigmentation in the offspring. The possibility of albinism must be considered.

RECURRENT ATTACKS OF GLOSSITIS

To the Editor:—*A female, aged 25, has recurrent attacks of glossitis associated with pain and burning sensations. The dental examination is normal. Smears of denuded areas are negative. It is felt that this is a form of allergy. Avoidance of coffee and tomatoes results in remission, but there has been recurrence.*

Nathan Sedofsky, M.D., Brooklyn, N. Y.

Answer.—There are many types and causes of glossitis. The description is most suggestive of so-called Moeller's glossitis. As a rule, in this condition there are intensely red, well-defined irregular patches in which the filiform papillae are thinned or absent and the fungiform papillae are swollen. Exfoliation of the superficial layer of the epidermis occurs in these patches. The condition is characterized also by burning, pain, and sensitivity to irritants. The condition is chronic but is characterized by remissions and exacerbations. The individual lesions may remain for long periods of time or regress and be replaced by new patches. The cause is unknown. Treatment is unsatisfactory, and the prognosis as to cure is poor.

ABSENCE OF FAT IN BODY

To THE EDITOR:—*Postmortem examination of a 48-year-old woman who died of lobar pneumonia revealed extreme wasting of subcutaneous tissues. The musculature was intact. There was no subcutaneous fat whatever, and the lobules of the breast stood out sharply. Further examination disclosed complete absence of adipose tissue on or within the internal organs. The heart was small. Microscopic examination showed total absence of adipose tissue in the breasts and only a few fat cells in the bone marrow. Please suggest possible causes.* *M.D., Florida.*

ANSWER.—Thorough search of the literature and correspondence with authoritative pathologists gives no indication of the existence of a condition in which there is an anomalous absence of fatty tissue as opposed to atrophy of intracellular fat. One pathologist has inquired whether the patient had ever been operated on and, in such case, if the condition noted at postmortem examination had been observed.

DROWNING IN FRESH WATER

To THE EDITOR:—*A young, healthy man died from pulmonary edema about three hours after what appeared to have been a satisfactory recovery from submersion for an uncertain period of time in fresh water (chlorinated swimming pool). Please give information concerning blood dilution, electrolyte changes, and hemolysis in similar cases. What treatment is suggested for this condition?* *M.D., Pennsylvania.*

ANSWER.—Death from drowning in fresh water is, in most instances, due to aspiration of a large quantity of liquid, which rapidly passes across the alveolar membrane and produces marked hemodilution. Within minutes, the sodium level may drop to 40 mEq. per liter. The hypotonic plasma produces rapid hemolysis, and potassium levels rise despite the hemodilution. Ventricular fibrillation due to potassium intoxication as well as to anoxia is a common cause of death, which often occurs within four or five minutes. Death may occur later as the result of pulmonary edema which is principally due to alveolar damage from struggling, aspiration, and anoxia. It should be emphasized that the alveoli are filled not with transudate but with a viscous, frothy fluid which contains large quantities of serum proteins. Congestive heart failure and neurogenic influences may contribute to the edema, and lower nephron nephrosis can be a late sequel.

Treatment should be directed toward restoration of respiration, with all possible speed, in order to correct anoxia. A blood count should be obtained and electrolyte levels measured. Partial restoration of normal values should be attempted by whole blood transfusion and administration of hypertonic sodium chloride solution (3 to 5%), with use of venesection to avoid hypervolemia.

SURGERY IN INTRAVENTRICULAR ISCHEMIA

To THE EDITOR:—*A man, aged 49, has had intraventricular block since 1949 and on two occasions has experienced episodes of acute left ventricular insufficiency. At present he is under appropriate medical treatment and his condition is fully compensated. What is the possibility of cardiac surgery improving blood supply to that area of the heart?*

Ruben Gandelmann, M.D.
Rio de Janeiro, Brazil.

ANSWER.—As yet, no operation has been shown to increase the circulation to the interventricular septum. In fact, it is open to question if any operation as yet performed significantly increases the circulation to any portion of the myocardium, with the possible exception of thromboendarterectomy in certain carefully selected cases of coronary heart disease with angina pectoris.

INHERITANCE OF HYPOTHYROIDISM

To THE EDITOR:—*What are the chances of hypothyroidism developing in a newborn infant (first pregnancy) if the mother has been hypothyroid for many years? The mother has a basal metabolic rate reading of -12% after taking ¼ grain (15 mg.) of thyroglobulin three times a day for several years. Would another form of thyroid extract be more effective? Should a larger dose be used during pregnancy?*

Philip Leavitt, M.D., Surfside, Fla.

ANSWER.—Hypothyroidism during pregnancy does not produce thyroid deficiency in the infant except in those instances in which the mother has iodine deficiency. Goitrous cretinism, a rare familial disease, may be transmitted from the mother to her children. Thyroglobulin is as effective as other forms of thyroid substance in the treatment of hypothyroidism. In most instances, pregnancy is not an indication for increasing thyroid medication.

CHILDHOOD IMMUNIZATION SCHEDULE

To THE EDITOR:—*If a child receives one diphtheria-pertussis-tetanus injection and fails to return for 8 to 10 months, should the series be started anew, or may he take the second injection and go on from there? The same information is desired concerning poliomyelitis immunization. How long an interval is allowed between injections before the effect is lost?*

Jackson Herbert, M.D., Portsmouth, Ohio.

ANSWER.—Experience with diphtheria and tetanus toxoids has shown that satisfactory immunity is obtained when injections are given at intervals of not less than one month or more than three or four months. Pertussis vaccine gives best results when the interval between injections is not longer than six weeks. The length of time required for the effect of a single injection of vaccine to wear off is not precisely established but is probably a matter of months for the above vaccines as well as poliomyelitis vaccine. Two injections followed by a booster (at any interval) are effective for both tetanus and poliomyelitis. One injection in the first few months of life can be counted on to provide a minimal effect up to 8 to 12 months of age. It would seem satisfactory to finish the primary series with two injections with a quadruple antigen, if the child is under one year of age. The booster at 12 to 18 months would be given as usual. For children aged 1 to 7 it would probably be better to give a series of three injections of a quadruple vaccine followed by a booster of poliomyelitis vaccine in one year and a booster of quadruple vaccine at 4 to 5 years of age. The above suggestions are necessarily arbitrary but on the available evidence should produce satisfactory immunity without excessive duplication.

SJÖGREN'S SYNDROME

To THE EDITOR:—*The question concerning the treatment of a woman with rheumatoid arthritis and deficient salivation* (THE JOURNAL, *June 27, 1959, p. 1136) may have an answer in an article reported in the* British Medical Journal, *June 13, 1959, p. 1512. Antimalarial medication produced satisfactory improvement in 14 of 25 patients with Sjögren's syndrome. Antimalarial drugs have been given to patients with rheumatoid arthritis and systemic lupus erythematosus, and, since Sjögren's syndrome may be a related disease, these medicaments might improve the condition of the patient referred to in the original query. The British investigator noted, as did the consultant to* THE JOURNAL, *that no treatment for Sjögren's syndrome is entirely satisfactory.*

George X. Trimble, M.D.
1401 Chestnut Ave.
Long Beach 13, Calif.

SCIATICA

To THE EDITOR:—*I have read the question and answer relative to sciatica in* THE JOURNAL, *Feb. 28, 1959, page 1016, and wish to suggest a possible diagnosis and treatment. The nocturnal pain with little diurnal disability or discomfort has been observed by me in several patients. All have been men who have consistently carried articles such as pocketbooks, keys, and folded handkerchiefs in a hip pocket. Frequently the patient had been erroneously considered to have arthritis or other related diagnosis. The initial symptom is poorly localized pain, which may become severe at night. It is first noticed in the knee and thigh regions, and there is occasional spread into the hip region.*

The only positive finding consists of localized tenderness over the sciatic nerve with some duplicated pain on deep palpation between the ischiatic tuberosity and trochanter. The findings suggest physical trauma to the underlying nerve as the cause, and it has been of interest to find that the symptoms subside within a few days with removal of the offending pocket article and use of reasonable care to minimize local pressure to the area when sitting. The patient should be cautioned to avoid the error of transferring the contents to the other pocket. A folded handkerchief may produce symptoms on the opposite side during the treatment, since there is a shifting of weight in the sitting position from the painful side.

Edward B. Hopper, M.D.
Naval Supply Center
Oakland, Calif.

The above comment was referred to the consultant who answered the original question, and his reply follows.—ED.

To THE EDITOR:—*The observation is interesting. It is difficult to realize that in the standard suit an object in the hip pocket could produce a pressure neuritis of the type described. In neurological diseases where there is wasting of the gluteal muscles, a pressure neuritis of direct pressure on the ischiatic tuber or the emergence of the sciatic nerve at the sciatic notch has caused occasional pain and neuritic symptoms. The proof of the contention would lie in the immediate relief of pain by removing the objects from the pocket on the affected side; therefore, one must assume that this oddity exists.*

GOVERNMENT STUDIES POLIOMYELITIS DATA

The Public Health Service declared that the sharply increased incidence of paralytic poliomyelitis this year is a cause for serious concern. "An explanation for this failure of effective control is urgently needed," said the agency's Communicable Disease Center in a report to health officers.

Although there were hopes for a progressive decline in the incidence of poliomyelitis, the rate this year will top that for the past two years and perhaps reach that for 1956, the agency said. However, with only preliminary data on hand, "evidence points strongly to the conclusion that the effectiveness of the Salk vaccine has been maintained.

"The possibility of a basic change in the ecology of the poliovirus deserves intensive study," said the report.

Until 1956, PHS pointed out, poliomyelitis attacked large areas, irrespective of race or socioeconomic status. However, since then, the incidence has been concentrated increasingly in slum areas, especially among Negroes.

"It is already clear that utilization of the vaccine in certain well-defined lower economic . . . ethnic groups has been wholly inadequate," the report stated.

"The excessive attack rates observed in some of these groups suggests the possibility of basic changes in the ecology of polioviruses such as the prevalence of particularly virulent strains or new and subtle social and environmental factors facilitating the spread of the virus in special groups. These possibilities warrant intensive study."

The report came as the incidence of poliomyelitis decreased for the second week in a row. For the week ending Sept. 12 273 paralytic cases of poliomyelitis were listed, compared with 291 for the week before. However, the total of paralytic cases through the latest week, 3,084, was higher than the 1,387 cases during the same period a year ago.

PHS noted that, as in previous years, the frequency of paralysis in relation to poliomyelitis vaccination remained consistent. Only 36% of persons who contracted poliomyelitis after four vaccinations were stricken with the paralytic type, compared with 79.3% of nonvaccinated persons.

For the year through the first week in September, 37.6% of persons with nonparalytic cases were those who had received three vaccinations or more; only 16.5% of the paralytic cases were in persons who had received three vaccinations. "The level of these frequencies," according to the report, "is markedly below the estimated levels of triply vaccinated persons in the population."

REFORMER OF MEDICAL EDUCATION DIES

Abraham Flexner, who helped reform medical education in this country almost 50 years ago, died in the Washington, D. C., suburb of Falls Church, Va., on Sept. 21 at the age of 92.

Known as "the father of modern medical education," Flexner in 1910 conducted an extensive investigation of 155 medical schools in the United States and Canada. His report charged that almost one-half the facilities were inadequate and were graduating poorly trained physicians. Only 31 schools were listed as completely acceptable in the "Flexner report."

The charges launched a revolution in medical education, with most of the unacceptable institutions closing down and other schools improving their standards. Flexner, an educator and not a physician, then developed a program for model medical training centers at universities. This was financed by the Rockefeller Foundation. Through the years, Flexner helped raise many millions of dollars for medical schools.

In 1936, the educator founded the Institute for Advanced Studies at Princeton University. A friend of the late Dr. Albert Einstein, he persuaded the physicist to come to this country.

HOUSING BILL BECOMES LAW

The catch-all housing bill, which set off one of the biggest debates of the session between President Eisenhower and the Democratic-controlled Congress, finally was signed into law after two previous housing measures had met vetoes.

The signature insured for this year a program aimed at encouraging construction of proprietary nursing homes. One provision of the bill authorized the Federal Housing Administration to guarantee private loans for construction of proprietary nursing facilities. Backed by the American Medical Association and the American Nursing Home Association, the plan is intended to stimulate private loans for such purposes and thus expand the number of homes.

Projects eligible for the program are those which state Hill-Burton authorities determine are in areas where there is a shortage of nursing-home facilities.

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, New York

REPORT POPULATION GROWTH RAISES DANGERS

A special congressional report recommended increased research on ways to curb an "explosive" world population that might reach 7 billion within 40 years. According to the study, made for the Senate Foreign Relations Committee by the Stanford Research Institute, "it is most likely that in the coming decade the explosive growth of population in many parts of the world will be accelerated by new scientific advances in public health and medicine."

The rising population, coupled with economic advancement and the competition of communist nations, "will lead to social unrest or even war unless the resources of science can be more effectively brought to bear on world problems of food, economic and social development, and population control," the report said.

"Current scientific developments indicate that a radical advance . . . such as a safe, effective, and inexpensive oral contraceptive could soon be available, if the comparatively small amount of research now under way in this field were stepped up," the report continued. "Greater than the physical and biological problems of birth control are the psychological and social problems to be solved, if population growth is to be checked by methods other than famine, disease, and war."

The most promising approach to date, the report said, is the development of an orally given contraceptive for women based on the ovulation-inhibiting effects of certain steroids. "Many scientists concerned with these problems believe that an inexpensive, easily used contraceptive with limited time effect and no adverse health effects could provide the means for effectively controlling population growth in those countries where national birth control policies are adopted."

The study noted that the Catholic Church permits the rhythm method under certain circumstances, and said, "It would seem reasonable that efficient rhythm birth control might be provided by a compound that would cause a slight ill-effect during the short monthly fertile period, making marital relations at least undesirable."

The study was issued as a matter of public information by the Senate committee and did not necessarily represent the views of any of the committee members.

FDA WARNS PUBLIC

The Food and Drug Administration asked all news mediums to publicize the following information:

"Women who have purchased the new 'Fashion Quick Salon-Tested Permanent,' manufactured by Richard Hudnut Company, are being warned by the company and the Food and Drug Administration not to use the product. It contains a neutralizer solution that is capable of causing severe and painful eye irritation lasting several days, should any of it get into the eyes.

"The manufacturer has done a good job of notifying retailers to stop selling the product and to put it aside until they can replace the neutralizer solution, but we are concerned about consumers who may already have purchased this product or who may buy it before it is taken off the shelves."

HEALTH INSURANCE BILL APPROVED

The House, by a top-heavy 382 to 4 tally, passed and sent back to the Senate a voluntary, contributory health insurance program that would cover an estimated 1,800,000 employees and their 2,700,000 dependents. Under the parliamentary procedure for the House amendments could not be offered. Many representatives had been prepared to attempt to add a program for already retired workers to the legislation.

However, it was still possible for such a program to be inserted in the Senate. Sen. Richard M. Neuberger (D., Ore.), chairman of a Senate post office and civil service subcommittee, held a one-day hearing on his own program for workers now retired.

The House bill was less costly to the government than the Senate version, calling for 107 million dollars annually compared with 145 million dollars, and did not contain some provisions of the Senate bill objected to by the administration. All affected organizations endorsed the legislation, including the American Medical Association, which also backed the principle of including the already retired under some voluntary programs.

EISENHOWER ASKS FULL CIVIL DEFENSE REQUEST

President Eisenhower urged Congress to appropriate the full 12 million dollars the administration sought to finance civil defense preparations by the various federal agencies. Congress had approved only 3 million dollars.

In a supplemental appropriations request for the remaining 9 million dollars the Chief Executive said, "Within the federal government there are departments and agencies peculiarly competent to cope with many of the diverse problems that would come with nuclear war. The request . . . *is for funds* to permit these specially competent agencies to contribute their experience, knowledge, and resources to the total effort required."

More than 4 million dollars of the supplemental money request was for the Department of Health, Education, and Welfare, with some of these funds earmarked for the U. S. Public Health Service for the training of civilian physicians in civil defense activities.

MISCELLANY

The House Judiciary Committe [illegible] tion establishing a National [illegible] Week. The American Medical Association's Committee on Toxicology backed the bill.

President Eisenhower signed into law bills increasing to three years presumption of service connection for multiple sclerosis and leprosy.

A board of 15 civilian and 2 military physicians has been appointed to compile the history of the Army Medical Service's role in internal medicine during World War II.

The House passed and sent to the Senate a two-year extension of the federal program to combat air pollution problems in urban areas. The bill authorizes 5 million dollars in federal grants annually for two years and extends the program, which was scheduled to expire June 30 next year.

ROLE OF HEREDITY, DIET, AND EMOTIONAL STRESS IN CORONARY HEART DISEASE

Henry I. Russek, M.D., Staten Island, N. Y.

A period of prolonged emotional strain associated with occupational responsibilities preceded the attack in 91 of 100 patients with coronary heart disease. In a comparable series of 100 patients with other diseases, only 20 had undergone this kind of strain. The pattern of insecurity, frustration, and restlessness extended beyond the primary vocation into secondary occupations and leisure activities. Taking 91/20 or 4.6 as a ratio measuring the importance of occupational stress, the author obtains comparable ratios of 2.7 for diet, 2.0 for tobacco, 1.7 for heredity, 1.3 for obesity, and 1.0 for lack of physical exercise as suggesting the relative importance of these factors in causing coronary heart disease in this group of patients.

THE frequency of coronary heart disease in different parts of the world has been found to be related to the mode of life rather than to the racial structure or age composition of the population.[1] Consequently, in recent years many investigators have sought to unravel the complex relationship between the incidence of clinical coronary disease and nutrition, physical exercise, overwork, emotional stress, and the use of tobacco and alcohol. Unfortunately, even in carefully designed epidemiologic studies, these factors are not easily separable. For example, the Bantu not only subsists on a completely different diet but lives under totally different cultural, social, economic, and emotional conditions than the American Negro. Similarly, dietary fat may be implicated in the differing death rates from coronary disease among Japanese living in Japan, Hawaii, and the United States, but other characteristics of the mode of life or environment, acting singly or in combination, may also be involved in these differences.

In assessing the role of physical exercise, the relationship of occupational categories to the clinical incidence of ischemic heart diseases may also be difficult to interpret. Thus, while bus drivers indulge in less physical exertion than conductors, the higher death rates from this disease reported in the former group may result from the emotional stress of driving in modern traffic, or from obesity or other causes, rather than from a lack of physical exercise. Moreover, in the determination of emotional stress on the job, occupational titles can be misleading, since accurate evaluation must take into account not only the nature of the major form of employment but also secondary business en-

deavors, deviations from usual hours of work, other activities pursued during periods away from the job, and the total life situation itself. Since it is only the evaluation of the patient which can give a measure of the stress involved, the emotional reaction to employment and to other life situations must be determined. Inasmuch as persons experiencing nervous tension may eat proportionately more calories in the form of fat, consume more tobacco and alcohol, and find less time for exercise, it is equally difficult to separate emotional stress from other possible extraneous etiological factors in the pathogenesis of atherosclerosis and coronary thrombosis.

Dietary Fat and Hypercholesteremia

Despite such inescapable problems, there is sufficient evidence from experimental and epidemiologic studies to warrant acceptance of the view that excessive ingestion of fat is causally related to clinical coronary artery disease. In animals there seems to be a parallelism between hypercholesteremia and atheromatosis. In humans, however, there are so many exceptions to such a correlation that factors other than a high blood cholesterol level must also be concerned. Certainly there is no constant relationship between the intensity and duration of hypercholesteremia and the time of onset, or severity, of atherosclerosis. It is also recognized that the relative susceptibility of the coronary arteries to atherosclerosis at any level of plasma cholesterol is modified by sex, heredity, and other factors. Similarly, the effect of diet on blood lipoprotein patterns is influenced by genetic differences in metabolism and by endocrine and nervous response to stress. Thus, it is evident that the atherogenicity of excessive ingestion of fat and of hypercholesteremia itself must be dependent on an interplay with other important factors.

Emotional Stress and Personality Factors

In recent years there has been strong denial of any scientific basis for the clinician's impression and layman's conviction that mental stress or emotional disturbances predispose one to coronary artery disease. Nevertheless, more than a decade ago various authorities independently described a constellation of personality traits in patients with coronary artery disease characterized by "compulsive striving, hard work, self-discipline and great need to get to the top." [2] In such persons they found that achievement of objectives brought no sense of satisfaction or relief from tension. Recently Wolf [3] has elaborated on this character structure and has emphasized the failure of the coronary-prone subject to enjoy "rest periods of satisfaction" between achievements. He has compared such persons with Sisyphus, a mythical king, who was forever condemned to roll a boulder up a mountain only to have it slip from his grasp within a hairsbreadth of the summit, so that his labors had to be endlessly repeated.

Occupational Stress—Emotional

If endowed with these traits, as alleged, the young candidate for coronary disease may possibly be distinguished from controls by occupational achievement or type of position held. The careful studies of Gertler and others [4] and Yater and coworkers [5] have, in fact, demonstrated a significant difference in the kind of positions held by young patients with coronary disease as compared with controls. The young patient, they found, almost always had occupied a position demanding responsibility and frequently one associated with emotional stress. Moreover, it is noteworthy that Weiss and associates,[6] as well as others, have reported that gradually mounting tension of emotional origin, months or years in duration, occurred prior to the onset of coronary occlusion in a large segment of the patients coming under investigation.

My own observations with Zohman [7] are in accord with these findings. In a group of 100 coronary patients under 40 years of age, prolonged emotional strain associated with job responsibility preceded the attack in 91% of cases, as compared with 20% for controls. In the coronary group, 25% had been holding down two jobs and an additional 46% had worked 60 hours or more per week for long periods immediately preceding the onset of symptoms. In another 20%, there was unusual fear, insecurity, discontent, frustration, restlessness, or inadequacy in relation to employment. Although positions of responsibility and jobs requiring pressure to make deadlines were significantly more frequent in the coronary group than in controls, in a great many instances stress assumed significant proportions only as a result of too many hours of work or as a consequence of secondary vocations or activities pursued during "leisure" hours.

Behavior Patterns

Friedman and Rosenman [8] recently compared three groups of men selected solely according to the behavior pattern which they routinely manifested in the performance of their work. One group exhibited compulsive striving, inclination to compete, desire for recognition, continuous involvement in deadlines, and unusual mental and physical alertness. A second group manifested a behavior pattern essentially the converse of the first. A third group was similar to the second but the behavior pattern was complicated by a chronic state of anxiety or insecurity. Friedman and Rosenman found that clinical coronary artery disease was seven times more frequent in the group manifesting an intense, sustained drive for achievement. It is noteworthy that more than 80% of the subjects in this group exhibited a behavior pattern characterized by "excessively rapid body movement, tense facial and bodily musculature, explosive conversational intonations, hand or teeth clenching, excessive unconscious gesturing and a general air of impatience."

While a significant proportion of our young coronary patients did manifest some or all of these characteristics, this description, as well as that of others, presents a caricature rather than a portrait of the average coronary patient under the age of 40 in our series. The majority did not exhibit such easily recognized outward behavior characteristics. In fact, most of the young patients under observation have shown a striking degree of self-control, dignified reserve, and outward complacency during interrogation. In most of these, psychological factors would have remained unrecognized had a special inquiry not been made regarding their presence.

In almost every instance we found the young coronary patient to be a victim of overwork, often as a result of an unrelenting drive, an intense desire for recognition, or a profound sense of obligation to his employer, his family, or others, but more commonly simply as a consequence of meeting life's challenges with maximum and unstinting effort. It was apparent that these patients had been compulsive about time, overmeticulous, and "blind" to their own stress end-point. They were often concerned about trivia, impatient with subordinates, and worrisome. As perfectionists they frequently chose to do the work themselves rather than to delegate it to others. Being "stress-blind" they took on more responsibilities at an occupational, social, or domestic level than good judgment appeared to dictate, minimized their symptoms, and neglected prudent rules of health. Perhaps the most characteristic trait of the young coronary patient, however, was his restlessness during leisure hours and his sense of guilt during periods of "relaxation." As a consequence, he rarely took vacations, and such leisure time as he did possess was frequently regimented by obligatory participation in an assortment of social, public, or educational activities.

Behavior Patterns and Occupational Demands

All types of occupations were well represented in the coronary group, and there was no indication that premature coronary artery disease is restricted to any specific level of vocational endeavor. The findings appear to indicate that emotional stress of occupational origin as well as ambitious goal-directed traits within the person may be causally related to coronary heart disease in all socioeconomic strata of our society. While emotional stress due to overwork was often a consequence of the nature and demands of the job, it was more frequently found to be a by-product of domestic obligations, multiple goals, an established behavior pattern within the person, or a combination of these. It appeared obvious, therefore, that occupational titles alone were unreliable from the standpoint of correlating epidemiologic data with any conclusive effects of occupation. Twenty-five per cent of the 100 young patients in our coronary group had been holding down two jobs prior to their illness, and, in many instances, the secondary occupation was totally different from the main type of employment. Moreover, we observed, as did others,[9] that the stress and strain of employment may be assessed differently "by the community at large and by the individual jobholder himself." Just as there are all degrees of stressful experiences, there are all gradations of resistance and of sensitivity of the person. Consequently, only careful appraisal of the individual reaction to these experiences can provide an index for quantitating stress factors.

"Contradictions" to Emotional Stress Theory

It has been claimed that racial groups in various geographical areas (Korea, Japan, Yemen) who subsist on relatively low-fat diets have appeared to exhibit a relative immunity to coronary disease despite obvious emotional stress in their patterns of life. Since this immunity seems to be lost when high-fat diets are ingested, the role of the emotions has been relegated to a position of secondary significance by some observers. On the other hand, the young coronary patients studied by me with Zohman[7] could be more readily differentiated from the control subjects by evaluation of occupational stress than by measurement of differences in fat intake, hereditary influences, obesity, tobacco consumption, physical activity, or other factors (see table).

Percentage Incidence of Various Factors in Subjects with Coronary Disease and Control Group[*]

Group	Heredity (Positive)	High-Fat Diet	Stress and Strain (Occupational)	Obesity	Tobacco[†]	Lack of Exercise
Coronary disease	67	53	91	26	70	42
Control	40	20	20	20	35	40
Ratio	1.7 to 1	2.7 to 1	4.6 to 1	1.3 to 1	2 to 1	1 to 1

[*] 100 subjects in each group.

[†] 30 cigarettes or more per day.

Thus, while there is abundant evidence that a high-fat diet predisposes population groups to coronary artery disease, it appears equally clear that, in persons so predisposed, emotional stress more than any other factor compounds this susceptibility. Yet, from epidemiologic studies, the conclusion seems inescapable that the lethalness of emotional stress is strongly mitigated, if not nullified, by subsistence on a diet low in fat. When food was rigorously rationed during the occupation of Norway and the Netherlands, for example, there was no general increase in cardiac death rates, according to available statistics, in spite of an obvious increase in emotional tensions. Similarly, the victims in concentration camps enduring indescribable hardships have not appeared to show a greater incidence of coronary disease.

While these observations indicate that emotional stress cannot be the sole factor in the etiology of coronary atherosclerosis, they do not exclude it as a major influence in the pathogenesis of this disorder in the American male and other susceptible groups subsisting on a high-fat diet. Indeed, while emotional stress appears to be well endured on a low intake of fat, most of the lethalness of a high-fat diet in our society would seem to be dependent on the "catalytic" influence of stressful living.

Stress and the Sympathetic Nervous System

At present, there is no clear understanding of the manner in which emotional stress may lead to clinical coronary artery disease, but numerous clues have been uncovered. Stress reactions are commonly associated with fluctuations of epinephrine, hypothalamic overactivity, and cortical and autonomic imbalance. In such illnesses as hypertension, colitis, asthma, and peptic ulcer, there are fairly well understood neural pathways and circuits involving the autonomic nervous system through which emotions can affect smooth muscle, glandular secretions, or both. In like manner, as a result of stress, sympathetic adrenergic effects on vascular tissue metabolism may contribute to atherogenesis to a much greater extent than is being generally appreciated.[10] Since epinephrine and arterenol (from the sympathetic nerve terminals) are potentially injurious to the vascular tissue, an excess of these hormones, by primarily damaging the intima, may prepare the soil for subsequent lipid depositions.

Moreover, it has been found experimentally that the deposition of cholesterol in the intima is accelerated and intensified by epinephrine and that catecholamine-phospholipid compounds seem to possess a particular affinity toward arterial tissues. Raab and Humphreys[11] have shown that catecholamines diminish myocardial efficiency and, by wasting oxygen in a disproportionate fashion, are capable of inducing severe, potentially necrotizing myocardial hypoxia. Selye[12] more recently has succeeded in producing massive, infarct-like necroses in the myocardium of various experimental animals, including the primate, by sensitization with certain corticoids and exposure to a variety of stressors. At present it is unknown whether a relationship exists between these lesions and the cardiac infarcts of man.

Stress and the Endocrine System

Since there is a close relationship between nervous stimuli and endocrine gland function, emotional stress acting through the cerebral cortex and hypothalamus may exert important effects on the endocrine system. Considerable evidence attests to the fact that the maintenance of normal cholesterol metabolism and of the coagulation-fibrinolysis system can be disturbed by stress-induced alteration of the physiological endocrine balance.

A number of investigators, as well as our own group, have observed striking elevations of the serum cholesterol level during transient stressful life situations. Bogdonoff and associates[13] have also shown that emotional episodes cause a rapid mobilization of nonesterified fatty acids from the body tissues into the circulation and have obtained similar results with infusions of epinephrine and arterenol. Although the mechanisms underlying such responses have not been clearly elucidated, hyperlipemia so evoked is believed to "provide metabolic substrate for the aroused organism."

In this regard, Seifter[14] and associates have shown that various forms of stress stimulate the anterior pituitary to discharge ACTH, the latter stimulating the adrenal cortex to discharge glucocorticoids; the corticoids then stimulate the posterior pituitary to release a lipid-mobilizer substance which acts on the fat depots to release neutral fats into the portal circulation. If the liver is not capable of handling this fat load, neutral fat is discharged into the peripheral circulation in association with cholesterol, resulting in a generalized hyperlipemia. It appears possible, therefore, that the mobilization of lipid from the fat depots by this mechanism may be an important cause of hypercholesteremia and coronary atherosclerosis in many of the patients seen in clinical practice.

The blood-clotting elements have also been found to be susceptible to emotional stresses. Shortening of the clotting time and an increase in viscosity of the blood appear to be part of an adaptive response to combat in order to prevent blood loss. When this mechanism reacts excessively over a prolonged period of time, blood with increased coagulability and decreased fluidity may slow sufficiently in passing through narrowed coronary or cerebral arteries to produce thrombosis.

Stress and Clinical Coronary Artery Disease

From these findings it would seem that prolonged emotional stress acting through the cerebral cortex and hypothalamus via neurohormonal and hormonal mechanisms may contribute not only to the initiation and progression of atheromatosis but also to its sequelae. Thus, metabolic changes in the vascular wall leading to an increase in its lipid receptiveness, elevation in blood cholesterol level, augmentation of myocardial oxygen requirements, and increase in the coagulability and viscosity of the blood appear to be implicated both in the adaption to stress and in the pathogenesis of clinical coronary artery disease. Wolff[15] has stated that "man, feeling threatened, may use for long term purposes devices designed for short term needs. They are not designed to be used as life long patterns and when so utilized may damage structures they were designed to protect." In many instances, therefore, atherosclerosis and coronary heart disease may represent a maladaptation syndrome in which the organism already oversupplied with circulating fat molecules (metabolic defect, dietary indiscretion, or both) useful in "combat" remains in a chronic state of mobilization for "fight or flight" as a result of stressful life situations. While mechanisms so evoked appear innocuous in "immune" groups subsisting on a low-fat diet, these adaptive devices greatly augment the atherogenicity and lethalness of excessive ingestion of fat and hypercholesteremia.

Failure to recognize the profound effect of socioeconomic stress on bodily function and human behavior in epidemiologic studies has greatly exaggerated the role of dietary fat per se in the etiology of clinical coronary heart disease. Although excessive ingestion of fat may impair lipid metabolism, prolonged emotional stress appears not only to augment profoundly this derangement but also to increase the receptivity of the vascular walls to cholesterol and to hasten the clotting of blood. The high intake of fat and the stressful patterns of living commonly observed in populations which are economically privileged must therefore be recognized as a highly lethal combination.

From all the evidence, it would appear that there are three major predisposing factors in the initiation and progression of coronary atheromatosis in young adults; namely, heredity, a high-fat diet, and emotional strain. Without exception, one or more of these factors was present in every patient in our coronary group, whereas none of these influences was observed in 24% of the control subjects. At least two of the major factors were evident in 95% of the coronary patients, as compared with only 12% of the control subjects. Emotional stress, usually associated with job responsibility, however, appeared to be far more significant in the etiological picture of coronary disease in young adults than heredity, the quantity of fat ingested, or other factors under consideration (see table).

Tobacco Consumption

A strong and consistent relationship has been found between cigarette smoking and coronary heart disease mortality. Our own studies have shown that smoking was not only more prevalent in the coronary group but also that twice as many of the coronary patients as compared with controls were heavily addicted to the use of tobacco. It would seem, therefore, that tobacco smoking is either an etiological factor in coronary heart disease or merely a manifestation of the inner tensions which beset the coronary-prone subject. I have found a close correlation between the quantity of tobacco smoked and the changing pressures of the life situation in the individual case. Moreover, among persons exhibiting a behavior pattern found to be associated with a high incidence of coronary atherosclerosis, Friedman and Rosenman[8] observed no "pathogenic relevance" between cigarette smoking and clinical coronary disease, despite the fact that smoking was more prevalent in this susceptible group than in controls. The greater consumption of tobacco by the candidate for coronary atherosclerosis, therefore, attests further to the significance of emotional factors in the pathogenesis of this disease.

Obesity and Physical Exercise

No support could be found for the view that obesity is an important etiological factor in the development of coronary heart disease in young adults. Manifest obesity was not significantly more prevalent in the coronary subjects than in controls (see table). Similarly, no correlation of regular exercise or the lack of it with normal health or early coronary disease was shown in our study. Moreover, few of the coronary patients could be considered to have possessed the "loafer's heart," as defined by Raab.[10] Consequently, these findings are inconsistent with a prevailing view that physical exercise reduces the tendency to develop arteriosclerosis. Nevertheless, the value of exercise, within physiological limits, in diminishing nervous tension must not be minimized.

Pressures of Leisure

Although ours is a civilization that enjoys more leisure than any in history, the majority of us in reality work harder—at something—than we have ever done before.[16] Not infrequently occupational demands are minimal compared to the pressures of our society. Much of the envied leisure time of Americans is regimented by participation in a variety of social, educational, and civic activities. Such obligatory use of leisure is not satisfying and may represent a poor antidote for the emotional stresses of daily business competition.

Clinical Implications

It is well recognized that emotional tension may result in compulsive eating, drinking, and smoking in many persons as compensation for anxiety. Moreover, it does frequently contribute to the failure to achieve daily exercise "by promoting fatigue and by forcing a man to make so many commitments that no time is found for exercise, such as walking."[16A]

Dawber[17] and his associates at the Framingham project have observed that an increased predisposition to coronary artery disease exists in persons manifesting hypertension, obesity, or hypercholesteremia. On the other hand, nervous strain of occupational, cultural, social, or domestic origin is known to elevate blood pressure, to increase the tendency to obesity, and to contribute to hypercholesteremia by psychic influences and by alteration of the functional characteristics of the mode of life. Consequently, even such indirect effects of emotional stress, barring all others, must elevate this factor to a position of significance in the etiological picture of coronary heart disease.

Some authorities have warned of the danger of assuming that emotional stress is an important agent in the etiology of coronary disease. They fear lest this view, by creating the belief that mental stress is always bad, may strip human life of its higher values and incentives and lead to unimaginative boredom. The presumption that the only alternative to a stressful existence whereby one lives a dynamic, purposeful, and happy life is retreat to a stress-less existence in which one vegetates is erroneous. Certainly Sir Thomas Lewis'[18] description of a prudent way of life, if followed, would not impair emotional and spiritual creativeness or the enjoyment of a full life:

> Very prudent people live quietly and moderately; they have their simple daily routine of work and pastime, enlivened by occasional excursions and entertainments, social gatherings and visits to and from their friends. They are temperate in their eating, taking no more than will maintain them in robust health, arranging their diet to consist chiefly of plain good food, relieved occasionally of its monotony by a more elaborate, but not heavy meal. They are regular in their habits of work and exercise, and in their mealtimes. They are strictly temperate in their drinking. They control their emotions and their passions. They avoid all forms of excess. They use tobacco little if at all. They welcome the freshness of abundant air and open spaces, delighting in the feelings of invigoration that accompany active exercise; they love the warmth of sunlight playing on their skins and the sleepiness of healthy fatigue. These are habits that few people in industrial countries now adopt, that fewer still maintain. The cares and distractions of an increasingly complex life, indoor or sedentary occupation, advancing years and decreasing energy interfere less or more, and the prudent rules are neglected; neglect is the easier because the penalties, owing to the body's great power of resistance to disease, are uncertain in their incidence and often long deferred.

Healthy habits would become more prevalent if the consequences of their neglect were more immediate and variable. Since diet and mode of life appear all-important in the prevention and control of coronary heart disease, and since one cannot reasonably anticipate adoption of the Bantu's dietary regimen, efforts at reduction of stress in the American way of life should prove most rewarding. Indeed, healthy habits, an optimistic philosophy, and the sound use of the abundant leisure which has made us the envy of the world might well neutralize or retard the atherogenic mechanisms which appear to be accelerated by the "stress and strain" of our daily struggle for existence.

CURRENT CONCEPTS OF THE MANAGEMENT OF OTITIC INFECTIONS

Joseph L. Goldman, M.D.
and
Harry Rosenwasser, M.D., New York

Although the incidence of mastoid infections has diminished greatly during the past two decades, in our experience the incidence of complications has increased considerably. Recognition of these complications has become more difficult since the advent of antibiotics because of their insidiousness and accompanying obscure clinical pictures. These drugs often provide a false sense of security while life-threatening situations are developing. Antibiotics and chemotherapy must be used judiciously in otitic infections with the view not to mask complications which are impending or have occurred. The need for accurate diagnosis, bacteriological examination, myringotomy when indicated, and rational therapy in general has not been obviated by the use of antibiotics in the management of patients with otitis or mastoiditis.

The great decrease in the number of mastoid infections during the past two decades has not lessened concurrently the serious problems associated with these infections. Actually, not only has the incidence of major complications increased proportionately but their recognition has become more difficult. This is the result of the promiscuous and widespread use of antibiotics and chemotherapy by general practitioners, internists, and pediatricians and also by otolaryngologists. Phases of this subject have been discussed by Tamari and Henner,[1] Henner,[2] Courville,[3] Nielsen,[4] Silcox,[5] Rosenwasser and Adelman,[6] Morrow,[7] and many others; yet this problem seems to show no sign of improvement. Because of some of our recent experiences, we believe that it is important to restate at this time these principles in the management of otitic infections.

What are the complications that can be obscured by antibiotics and sulfonamides? Perisinus, epidural, and brain abscess, bacterial meningitis, primary jugular bulb and lateral sinus thrombosis, and labyrinthitis compose the frightening list of diseases which can, but should not, evade recognition. In our experience otitic complications now occur in about 40 to 50% of mastoid infections as compared to 5 to 10% prior to the era of antibiotics and chemotherapeutics.

One of the most troublesome consequences of the indiscriminate and injudicious use of antibiotic and chemotherapeutic agents has been the development of variable micro-organisms as etiological agents and of resistant strains of these micro-organisms. At one time 90% of mastoid infections in our institution were caused by the beta hemolytic streptococcus, which is usually sensitive to penicillin. We must now contend with many infections in which Staphylococcus aureus and gram-negative micro-organisms, such as the Hemophilus influenzae, Proteus vulgaris, and Pseudomonas aeruginosa, are the infecting agents. Many of the Staph. aureus micro-organisms have become resistant to most antibacterial drugs. Therefore, it must be realized that in otitic infections it has become essential first to determine the infecting micro-organism and the sensitivity of this micro-organism rather than to rely on the administration of penicillin and more penicillin. Also, it must be appreciated that antibiotics and chemotherapy are not foolproof. Mastoiditis is a bone disease which can smolder and spread while symptoms abate.

As a consequence of this absence of alarming symptoms and findings, patients are observed for prolonged periods. No longer can one rely on the septic febrile course, chills, and proved bacteremia in patients with sinus thrombosis or on hemicranial pain, profuse aural discharge, and persistent and exquisite tenderness in patients with perisinus, epidural, or brain abscess. Complications, such as meningitis, labyrinthitis, and facial paralysis, appear without the usual warning symptoms of progressive mastoid disease.

Advanced Mastoid Disease

It has been our experience that advanced mastoid disease can exist without the symptoms and signs which two decades ago were considered necessary in order to make the diagnosis of suppurative mastoiditis. We have repeatedly seen disease of the mastoid bone requiring surgery in patients having an intact, flat tympanic membrane with landmarks visible and with no fever or mastoid tenderness. In addition, roentgenograms of patients who have received antibiotics for long periods of time for otitic infections may offer misleading information. Serious infection may be present in the

mastoid bone under these circumstances, without the usual evidence of destruction. Roentgenograms in these instances may show cloudiness without evidence of bony destruction; yet extensive infection may exist in the mastoid bone. Operative intervention in such cases often discloses multiple areas of infection with softening but no dissolution of the bony septums. The following two cases are presented to illustrate this point.

CASE 1.—A 5-year-old boy was admitted to the hospital with a seven-week history of fever after an acute upper respiratory infection, during which time he was treated with penicillin and other antibiotics. On admission of the patient the tympanic membrane was flat and all landmarks were present. There was a small area of tenderness far back on the mastoid bone over the region of the emissary vein. Roentgenograms of the mastoid region were reported as showing "cloudiness of the mastoid but no evidence of destruction."

Operation revealed extensive bone destruction and creamy pus oozing from granulations over an exposed lateral sinus and middle fossa dura. Streptococcus hemolyticus was isolated from the pus. This patient had a badly diseased mastoid with perisinus and epidural abscesses, even though the tympanic membrane was normal and the roentgenograms exhibited minimal findings. Penicillin had been administered for seven weeks.

CASE 2.—A 7-year-old boy became ill seven weeks prior to admission to the hospital, with pain in the right ear which disappeared after three days of administration of penicillin. Two weeks later pain returned in the right ear, and the temperature rose to 107 F (41.7 C). The patient was again treated with penicillin for several days. He was well until four days before admission, when there was a recurrence of earache, this time associated with vomiting and temperature of 103.6 F (40 C). Penicillin therapy was resumed. Diplopia appeared on the day preceding admission.

The positive findings on admission were a dull, intact right tympanic membrane with all landmarks present except the light reflex; tenderness over the right mastoid bone; and a paresis of the right sixth cranial nerve. A roentgenogram showed "diffuse haziness overlaying the entire right mastoid region, obliterating the intercellular septums, and obscuring the pneumatic structures; there was no definite evidence of bone destruction." Cerebrospinal fluid was normal. While the patient was in the hospital, right hemicranial headache increased as well as general malaise. A mastoidectomy was performed two days after admission. All the cell walls appeared soft and necrotic. In the region of the tip there was extensive necrosis of the cells with necrotic granulations. The lateral sinus plate was necrotic. There was an extensive perisinus abscess with an organized blood clot between the sinus plate and sinus wall.

After operation there was rapid disappearance of the signs of meningeal irritation. The paralysis of the right external rectus muscle cleared in two days. Culture of material taken from the mastoid cavity failed to yield any micro-organisms. This child had meningeal irritation secondary to mastoiditis with perisinus abscess which became evident after six weeks of intermittent and inadequate antibiotic therapy. The middle ear appeared innocuous and had never discharged.

Comment.—How can one be on guard as to the possibility of mastoid disease and its complications in this era of antibiotics? As previously stated, the infecting micro-organism must be determined and sensitivity tests made in every instance. Should an otitic infection persist behind an intact tympanic membrane, the secretion in the middle ear should be aspirated for culture. If evidence of an otitic infection persists after antibiotics or chemotherapy have been administered for a reasonable length of time, then the use of the antibacterial drug should be discontinued and the clinical course observed without the interference of such medication. As in the years before antibiotics were used, the element of time should play an important role in determining the course of management. For instance, since Staph. aureus is a particularly destructive micro-organism in mastoid disease, it is our opinion that it is much safer to perform a mastoidectomy early in the course of the disease, when this is the infecting micro-organism.

If an otitic complication is suspected, it is also wiser to permit the disease to manifest itself in its early stages rather than in an advanced state when life itself is threatened. At some point within the first few weeks after the onset of an otitic infection, it becomes imperative to know what is actually happening within the temporal bone. In this way adequate surgical procedures can be performed before the disease has progressed to a serious degree, if antibiotic therapy and chemotherapy have failed. Experience has proved that thorough mastoidectomy performed at the proper time is far less dangerous than procrastination or neglect when disease of the mastoid bone exists. We believe that this point of view is especially pertinent in our age of antibacterial therapy. It is indeed to the patient's and doctor's advantage to treat an uncomplicated mastoiditis rather than to cope with a masked complication.

We would like to mention two unfortunate patients whose clinical pictures were completely masked by prolonged antibiotic therapy and who ultimately died. One, a young girl, entered the hospital in coma with an extensive lateral sinus thrombosis and acute meningitis; the other, a young boy, was admitted to the hospital in coma with a large brain abscess.

Chronic Otitic Infections

Special reference should be made to chronic otitic infections. Years ago the acute exacerbations usually were caused by the common pyogenic micro-organisms, such as Str. pyogenes and Diplococcus pneumoniae, or occasionally by Staph. aureus. P. vulgaris, Ps. aeruginosa, and resistant Staph. aureus are now more frequently responsible for these infections. These micro-organisms in themselves increase the incidence of the complications which are commonly associated with exacerbations of chronic infections, namely, cerebellar abscess, meningitis, acute labyrinthitis, and facial paralysis, and they do not yield to antibacterial drugs as do Str. pyogenes and D. pneumoniae. The following two cases are offered as illustrations.

Case 3.—A 64-year-old man presented the complaint of pain in the left ear and left hemicranial headache of five weeks' duration. The ear had been discharging for a short time. The ear pain and headache had progressed until it became very severe. In the fifth week, dizziness and impaired hearing and buzzing appeared in the left ear. During the entire five weeks the patient had received penicillin.

Examination revealed marked nystagmus to both left and right, tenderness over the left mastoid, and conductive deafness in the left ear, but hearing was present. The ear drum was yellowish, with a marginal posterior superior perforation, and there was no discharge. Roentgenograms of the mastoids showed "no evidence of bony breakdown or abscess formation of the body of the mastoid" and a "completely apneumatic mastoid with slight enlargement of the antrum."

An endaural radical mastoidectomy was performed. The mastoid was sclerotic. A large cholesteatoma was found that had eroded the cerebellar and middle fossa plates and had caused partial necrosis of the labyrinthine capsule of the external semicircular canal. There were also infected granulations on the cerebellar and middle fossa duras. Culture of this mastoid yielded P. vulgaris.

An acute exacerbation of symptomless chronic middle ear disease caused by P. vulgaris had been treated with penicillin for five weeks, while headaches and labyrinthine symptoms increased. The findings in the middle ear remained minimal during this entire period. With eradication of the disease process, the patient made a complete recovery.

Case 4.—A 76-year-old man had had a mastoidectomy on the right performed 50 years before. He was well until six months prior to admission to the hospital, when he developed pain in the right ear, with discharge. Pain became progressively worse, headache supervened, and his poor hearing became further impaired. The patient received a variety of antibiotics during the entire six months.

On admission of the patient, the tympanic membrane was intact and dull and presented no landmarks. The roentgenogram showed the old mastoid defect. It was found that a probe could be passed through granulations on the posterior canal wall into the mastoid. Discharge obtained from this tract yielded Ps. aeruginosa.

At operation extensive disease was found in the remaining mastoid bone. There was necrosis of the posterior canal wall with necrotic granulations over the facial nerve. On the 17th postoperative day, the patient developed facial paresis, which became total. He was treated locally with neomycin sulfate. After three weeks the paralysis began to clear and ultimately disappeared.

This is an instance of a Ps. aeruginosa infection in an acute exacerbation of a previously operated on mastoid which was treated for six months with a variety of antibiotics. At no time was a culture or, more important, a sensitivity test done. In spite of treatment with a variety of antibiotics, necrosis of the posterior canal wall and exposure of the facial canal wall developed.

Comment.—The treatment of chronic otitic infections in recent years has been greatly influenced by such new procedures as tympanoplasty, with a view to improving hearing. When dealing with otitic complications, we believe that all effort should be focused on treating the complications, with the conservation or improvement of hearing of secondary importance. Needless to say, physiological function must not be sacrificed when it can be safely maintained.

The consideration of this subject would not be complete without a brief discussion concerning the present therapy of acute otitis media. The otolaryngologist is called on to treat the acute middle ear infection very infrequently. These infections are treated mostly by our medical confreres, especially the pediatrician, and the method of therapy is invariably the administration of penicillin, sometimes with other antibiotics, no matter how definite the evidence that pus exists under pressure behind the tympanic membrane. Those of us who have had the experience of exploring middle ears for conductive deafness have been impressed with the frequency with which adhesive processes and scar tissue have been found to enmesh the ossicles. These tissue reactions are most likely the result of previous infections. It is our opinion that purulent infections of the middle ear which are not properly drained, as is usually done when there is a collection of pus anywhere, may occasionally lead to alterations in the middle ear which can result in impaired hearing.

Again, because of the present variations in etiological agents in middle ear infections and in the sensitivity of these micro-organisms to antibiotics and the sulfonamides, it seems to us that the principle of drainage of acute middle ear infections by myringotomy as additional therapy should be stressed more than ever.

Conclusions

The incidence of serious and life-threatening complications in mastoid disease has increased considerably during the era of antibiotics and sulfonamides. This is largely due to indiscriminate and injudicious use of antibiotics and chemotherapeutic agents, the change in the causative micro-organisms in mastoiditis and the development of resistance of these micro-organisms to these drugs, and the false security which these drugs provide which results in unwarranted and undesirable prolonged therapy and observation.

HYPNOANALGESIA AND HYPNOANESTHESIA FOR CARDIAC SURGERY

Milton J. Marmer, M.D., Beverly Hills, Calif.

Hypnosis was used in connection with thoracotomy for heart disease in eight patients, the youngest being 10 and the oldest 58 years of age. The first six all received diphenhydramine, thiamylal, alphaprodine, either pentobarbital or secobarbital, and either succinylcholine or hexylcaine. The seventh required only thiamylal, succinylcholine, and hexylcaine. The eighth, a woman aged 42, underwent mitral commisurotomy after receiving only hexylcaine topically for endotracheal intubation and 30 mg. of succinylcholine intravenously for muscular relaxation; this patient was able to remove the tube herself, required no postoperative narcotics or sedatives, and manifested total operative amnesia. It is concluded that the reassurance which can be induced by hypnosis allays fear, anxiety, and tension more effectively than do the tranquilizing drugs.

Psychological factors play a large role in the total response of a patient to surgery. Anesthetists are often so busy with the mechanical and technical aspects of their specialty that they overlook some of the psychogenic elements which can also produce changes in the patient. Anesthetic dosage is dependent not only on the physical state of the patient but on his emotional configuration as well. As Kubie and Margolin[1] stated, "The action of drugs is never a simple function of either the chemistry of the drug or its dosage. The effects of identical doses of any drug administered to the same individual will vary, depending on the conscious and unconscious emotional processes at work in the patient."

Attitude of the Patient

Illness is something the average patient cannot cope with. He is usually beset by the fear of something unknown and, as a consequence, feels helpless and frightened. However much illness itself may be feared, an operation, and especially anesthesia, is even more dreaded and is likely to cause greater tension, anxiety, and apprehension. Anesthesiologists are well aware of cardiac and respiratory decompensation and have concentrated their training and practice on its prevention. Little attention, however, has been paid to the problem of psychological decompensation and its prevention.

From the Department of Anesthesiology, Cedars of Lebanon Hospital, Los Angeles.

Read in the Symposium on Common Problems before the Joint Meeting of the Section on Anesthesiology and the Section on Nervous and Mental Diseases at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 11, 1959.

Hospitalization produces sudden and drastic changes in the pattern of the patient's life. It is a strange environment where one is exposed to all the stresses which accompany the lack of privacy. This feeling of helplessness and abandonment fosters even greater anxiety and apprehension. Operations in early childhood may produce, as traumatic effects of these procedures, later phobic symptoms and feelings of having been drugged, gassed, or suffocated.[2] Sleeplessness, restlessness, and agitation are among the disturbances in emotional adjustment which have been described after surgery and anesthesia.[3]

Patients with Heart Disease.—Patients with heart disease who have to undergo cardiac surgery present a particular problem and challenge. The word "heart," as Wolff[4] expressed it, has become a symbol for the human spirit. Stress-producing life situations, in association with feelings of anxiety and fear, produce changes in cardiovascular and respiratory function. Under stress, the heart does not function normally. It functions inefficiently as to rate, rhythm, and coronary flow and takes a far longer time to return to the normal state. In fact, this is more operative under emotional stress than during physical exercise.[5]

Anything interpreted as a threat to life can produce bodily changes sufficient to destroy the organism. As has been pointed out by Wolf[6] the occurrence of various arrhythmias in association with emotional distress is quite familiar. However, what is not readily recognized is that atrial fibrillation and ventricular tachycardia may be induced by circumstances that have a stressful meaning to the patient. What can be expected in patients with already damaged hearts or compromised circulations? These patients have made a long-term adaptation to the progressive limitation of their activities, in order to provide for their emergency defenses.

Patients are incapacitated to varying degrees by heart disease. The way persons adjust to this disease depends on their total personality organizations and their life situations. On developing heart disease many patients have to alter their patterns of life. They are advised by their physicians to change their mode of living, including work habits as well as interpersonal relationships between members of the family. Since early childhood many of these patients have regarded this disability as a distinct threat to their existence. Most patients feel that, since they have been told all their lives to "take it easy," not to strain their hearts, and to be careful about everything they do, they cannot tolerate an operation on the heart. Isn't it dangerous? How can they survive?

These patients are especially fearful of being placed in this helpless situation while under the influence of anesthesia. They are concerned about the forthcoming operation and its outcome. They are also aware of the anxieties of their close relatives, although these may never have been verbalized. Many even feel the anxieties of the physicians who recommend the surgery. To get a patient to consent to the operative procedure many doctors must confront him with the seriousness of his disease for the first time. This further breaks down the patient's thin defenses and arouses even greater anxiety.

While it is true that the reaction to the disease is not the same in all persons and depends on personality structure and the degree of physical incapacity and the duration and severity of the illness, heart disease has a variety of complex effects and meanings to the patient. Cardiac disease is usually a serious ailment and often a chronic one. Its impact is great and it is accompanied by considerable psychological effects. The heavy emotional load a patient carries was clearly expressed by a well-known personality who said he was consumed with a "cold, clammy, clutching fear" prior to a thoracic operation.

Techniques of Anesthesia

Anesthesia for patients undergoing cardiac surgery requires the use of the least toxic medication and the lightest plane of anesthesia. In general, all that is needed for anesthesia in cardiac surgery is a combination of analgesia, amnesia, and muscular relaxation to provide the surgeon with a quiet field to work in.[7] Artusio,[8] in 1955, reported on ether analgesia for mitral valvulotomy and predicted that the analgesic state would be the narcosis of the future. Artusio obtained his results by allowing the patient to ascend from deep to light planes of anesthesia. Bailey and co-workers[9] also described a technique of anesthesia for cardiac surgery, which involved keeping the patient in a relatively light plane of anesthesia with barbiturates, narcotics, and muscle relaxants and administering 100% oxygen during most of the procedure. Sheiner[10] has described a light zone of anesthesia through which the patient is guided by suggestions. He stated that it was not possible to reach the light zones of anesthesia directly but that it was always necessary to deepen anesthesia to stage 3, plane 1, and then allow the patient to drift to the desired light state.

Hypnosis.—It is well known that deep anesthesia may significantly impair myocardial function.[11] The heart itself is relatively insensitive to pain from surgical intervention, and little analgesia is required for operations on the heart. The use of hypnosis offers a means of inducing a light plane of anesthesia in the cardiac patient without first exposing him to the hazards of deep anesthesia. Hypnosis is indicated in these patients, because it is a method which is extremely effective in overcoming the fear, anxiety, and apprehension which accompany the anticipated surgery and anesthesia. It is valuable as a means of sedation and can in many instances reduce the premedication and often completely eliminate it. It will aid in increasing patient cooperation and assist in postanesthetic recovery. The use of posthypnotic suggestion will contribute to a more pleasant, comfortable, and rapid postoperative recovery. Properly used, posthypnotic suggestion can be effective in producing operative amnesia and improving postoperative morale and motivation toward getting well.

Hypnosis can raise the pain threshold and reduce the postoperative need for depressant narcotics. The emotional state influences the thresholds of pain perception and reaction to pain. Pain perception is dependent on the integrity of relatively simple and primitive neural fibers. Reaction to pain, however, is related to the highest cognitive functions and depends on the suprasegmental integrative cortical levels. Pain and anxiety are reciprocally interrelated. Anxiety provides the soil in which pain can take root.[12] The threshold of pain perception can be raised by 40 to 50% through hypnosis.

The employment of hypnotic techniques, in combination with minimal amounts of chemical anesthetic agents (hypnoanalgesia), will reduce toxicity and lessen the dangers of cardiovascular and cardiorespiratory depression. It will enable the cardiac patient to undergo the rigors of surgery and anesthesia with less risk and greater safety. In rare instances, hypnosis alone is effective (hypnoanesthesia); this offers the greatest benefit and advantage to the patient.

Last year I [13] described the use of hypnoanalgesia for open-heart surgery in two children. I am reporting here further experiences with the use of hypnoanalgesia and hypnoanesthesia in cardiac surgery. The operative procedures include the closure of interatrial septal defects in three children and mitral commissurotomy in four adults, performed under hypnoanalgesia. Also, the first mitral commissurotomy performed entirely under hypnosis (hypnoanesthesia) is being reported.

The opportunity for the use of hypnosis is enhanced in persons undergoing cardiac surgery, because these patients are usually admitted to the hospital several days prior to the scheduled operation. This makes them available for interview by the anesthesiologist and presents him with the time necessary for the successful use of hypnotic techniques. The technique used should be one which is most suitable for the patient and one which seems most natural to the doctor and with which he feels most comfortable. I have found the most satisfactory technique in these patients to be a method of progressive relaxation. Relaxation will lower the state of tension and relieve the oppressive effects of the emotions on the bodily functions. Many of these patients can be hypnotized to some degree, but total and complete anesthesia requires a person capable of reaching a somnambulistic level of hypnosis.

During surgery an intravenous infusion is started in every patient to allow for the administration of fluids, blood, or any drug, should it be needed to maintain a smooth, safe course of anesthesia. No unnecessary risk is ever taken with any patient. Oxygen is always administered. No patient is exposed to possible noxious reflex action; for example, on laryngoscopy, the vocal cords and trachea are sprayed with topical anesthesia to prevent possible laryngeal spasm or vagal arrest during intubation. An airway is always inserted to allow for deeper and more adequate respiration. Endotracheal intubation may not always be as easy in a hypnotized as it would be in a totally curarized patient. Patients may often move. However, this does not interfere with the procedure. Furthermore, the patient has no memory of this. After intubation 100% oxygen only is administered. The patients tolerate the endotracheal tube without any difficulty.

From time to time small amounts of 0.2% succinylcholine solution may be added to the intravenous infusion, in order to facilitate the surgery by providing a quieter operative field. Under hypnoanalgesia minimal amounts of chemical anesthetic agents are needed, and under hypnoanesthesia no anesthetic agents are needed. When the operation is completed the patients are awakened gradually by dehypnotization after appropriate posthypnotic suggestions have been given, regarding postoperative comfort and relaxation and the ability to breathe deeply and to cough easily when requested to do so. Response to posthypnotic suggestions has been very satisfactory.

Report of Cases

Child Patients.—Children, because of their ability to project an image and create a fantasy, make unusually good hypnotic subjects.[14] The following cases involved three children, aged 10, 11, and 15, who were operated on for closure of an interatrial septal defect, under hypnoanalgesia.

CASE 1.—A 10-year-old girl was admitted to the hospital for surgical repair of an interatrial septal defect. She was seen two days prior to operation and was able to enter a partial hypnotic trance by means of an image-projection technique. The morning of surgery she was given as premedication pentobarbital sodium, 50 mg., and diphenhydramine (Benadryl) hydrochloride elixir, 1 dr. (4.5 cc.), at 6:30 a. m. She was brought to the operating room at 7:45 a. m. in a calm, relaxed state. At 8 a. m., after being placed on the operating table, she was rehypnotized in response to a given signal. A catheter was securely placed into the right antecubital vein and 75 mg. of thiamylal (Surital) sodium injected intravenously. Prior to intubation alphaprodine, 10 mg., and succinylcholine, 10 mg., were also injected intravenously. Endotracheal intubation was performed without difficulty and 100% oxygen administered throughout the procedure.

Prior to incision, at 8:30 a. m., 25 mg. of thiamylal was again injected. After a right-sided thoracotomy was performed, the child was put on cardiac bypass (pump oxygenator) at 11:37 a. m. The heart was opened at 11:39 a. m., and the interatrial defect was closed with silk sutures within four minutes. During the cardiotomy the child opened and closed her eyes on command. She was taken off the pump oxygenator at 12 noon and the operation was completed at 2 p. m. At the end of the procedure suitable posthypnotic suggestions were given and extubation was performed. The child was then awakened and was happy to know that the procedure was completed. She made an uneventful recovery and required minimal amounts of narcotic drugs postoperatively.

CASE 2.—An 11-year-old boy weighing 98 lb. (44.5 kg.) was admitted for surgical repair of an interatrial septal defect. He was seen two days before surgery and responded well to hypnotic suggestion. The morning of surgery he was given secobarbital, 50 mg., and diphenhydramine, 25 mg., as premedication. One hour later he was taken to the operating room and at 7:30 a. m. was rehypnotized by response to a prearranged signal. A catheter was securely placed in the right antecubital vein and 100 mg. of thiamylal sodium injected intravenously. Endotracheal intubation was performed without difficulty after the intravenous injection of succinylcholine, 20 mg., and alphaprodine, 10 mg., and 100% oxygen was administered throughout the procedure. After the necessary intravenous and arterial cut-downs were done, the operation began at 9:35 a. m.

Just prior to the incision an additional 10 mg. of alphaprodine was given intravenously. Right-sided thoracotomy was performed, and the boy was put on the pump oxygenator. The auricle was opened at 11:41 a. m. and closed at 12:12 p. m., during which time a large interatrial septal defect was satisfactorily closed. The operation was completed at 1:45 p. m. Appropriate posthypnotic suggestions were given and then the boy was asked to awaken. He was then asked to remove the endotracheal tube by himself. This he did with ease. He made an uneventful recovery.

CASE 3.—A 15-year-old girl weighing 115 lb. (52.2 kg.) was admitted to the hospital for surgical closure of an interatrial septal defect. She was interviewed the day prior to surgery and responded well to suggestions of relaxation but not to suggestions of anesthesia. An attempt was made to condition her to acceptance of cold, since the operation was to be performed under hypothermic anesthesia. Her response was difficult to interpret, but I nevertheless felt encouraged to go ahead. The morning of surgery she received as premedication secobarbital, 100 mg., and diphenhydramine, 25 mg. She was brought to the operating room awake but relaxed. At 10 a. m., with use of a hypnotic induction technique, a catheter was placed in her left antecubital vein and an intravenous infusion of 5% dextrose in water begun. Thiamylal sodium, 100 mg., was injected and again suggestions of well-being while cold were given. Endotracheal intubation was performed after the intravenous injection of 20 mg. of alphaprodine and 20 mg. of succinylcholine. Throughout the procedure 100% oxygen was given.

The patient was placed in an ice-water bath and after 30 minutes was taken out; her body temperature had reached 34 C (93.2 F). While in the bath the patient received an additional 30 mg. of succinylcholine and 100 mg. of thiamylal intravenously to prevent shivering. Her temperature leveled off at 32.5 C (90.5 F), and the operation was begun at 11 a. m. A right-sided thoracotomy was performed. The interatrial defect was successfully closed within four minutes. The operation ended at 2:15 p. m., by which time the patient's esophageal temperature had risen to 34 C. Warming was begun immediately after completion of surgery. When the temperature reached 36 C (96.8 F) the patient removed the endotracheal tube herself. Posthypnotic suggestions were given, relevant to well-being, comfort, and ability to breathe deeply and cough adequately. At 4 p. m. her temperature had reached 36.5 C (97.7 F) and she was taken to the recovery room in good condition. She made an uneventful recovery.

Adult Patients.—Adults, as well as children, can benefit from the use of hypnosis in combination with reduced doses of anesthetic drugs. In the following four patients mitral commissurotomy was performed under hypnoanalgesia.

CASE 4.—A 56-year-old woman was admitted for mitral commissurotomy. She was seen the night prior to surgery and responded well to hypnotic suggestion. The morning of surgery she received secobarbital, 50 mg., and diphenhydramine, 50 mg., as premedication. She was brought to the operating room awake but relaxed. For 15 minutes prior to induction of anesthesia the patient was given 100% oxygen to breathe. An 18-gauge needle was securely placed in a vein of the right hand and an infusion of 5% dextrose in water begun. At 9:20 a. m. 75 mg. of thiamylal sodium was injected intravenously. At the time the drug was injected the patient was again hypnotized. Under direct vision the larynx and trachea were sprayed with 5% topical hexylcaine solution. An endotracheal tube was inserted and 100% oxygen was administered throughout the procedure. Just prior to the incision, at 9:40 a. m., 20 mg. of alphaprodine was injected intravenously. The chest was opened at 10:20 a. m., at which time the patient was able to open her eyes on command. Valve fracture was performed at 10:52 and 10:57 a. m., and the patient was able to respond by opening her eyes, when asked to, after each fracture. The operation was completed at 12:15 p. m., and the tube was removed after posthypnotic suggestions were given. On extubation the patient was awakened. She responded in a most satisfactory way and made an uneventful recovery. Minimal doses of narcotics were required postoperatively.

Case 5.—A 52-year-old woman was admitted for mitral commissurotomy. She was seen two days prior to surgery and responded well to hypnotic suggestion. The morning of surgery she received secobarbital, 50 mg., and diphenhydramine, 50 mg. She was brought to the operating room awake but calm. Hypnosis was reinduced in the operating room and an infusion of 5% dextrose in water was begun intravenously. Thiamylal sodium, 100 mg., and alphaprodine, 20 mg., were injected intravenously. Endotracheal intubation was performed with ease after the vocal cords were sprayed with 5% topical hexylcaine solution. Throughout the procedure 100% oxygen was administered. Prior to incision an additional 50 mg. of thiamylal sodium was injected. The entire procedure took two hours, during which time the mitral valve was fractured three times. The patient was able to open her eyes on command after each fracture. At the end of the operation the patient was given appropriate posthypnotic suggestions and extubation was performed. Then she was asked to awaken, which she did immediately. Postoperatively she required minimal amounts of sedative drugs and made an uneventful recovery.

Case 6.—A 58-year-old woman was admitted for mitral commissurotomy. She was seen the night prior to operation and was able to respond to hypnotic suggestions only so far as relaxation was concerned. The morning of surgery she was given secobarbital, 50 mg., and diphenhydramine, 25 mg. A catheter was inserted into the right antecubital vein, and, during the induction of anesthesia with 150 mg. of thiamylal sodium, hypnosis was again attempted. In order to obtain proper visualization during laryngoscopy 20 mg. of alphaprodine and 30 mg. of succinylcholine had to be given intravenously. The operation lasted for two and one-half hours, during which time the patient received 100% oxygen only and an additional 50 mg. of thiamylal sodium. Mitral commissurotomy was performed successfully, and at the completion of surgery the endotracheal tube was removed. The patient was awakened soon thereafter. Posthypnotic suggestions were given prior to awakening but she nevertheless required average doses of postoperative narcotics. She made an uneventful recovery.

Case 7.—A 39-year-old woman was admitted for mitral commissurotomy. During the previous year she had had several episodes of cerebral embolization, from each of which she recovered. She was interviewed two days prior to surgery and found to be an excellent hypnotic subject. She was able to reach a deep trance level. She was seen again the next day and hypnosis was reinduced, with emphasis on producing anesthesia of the chest. She responded very well. The morning of surgery she was taken to the operating room asleep in response to posthypnotic suggestion. She was given no premedication. She was rehypnotized in the operating room in response to a prearranged signal. An intravenous infusion of 5% dextrose in water was begun and 100 mg. of thiamylal sodium was injected intravenously. Endotracheal intubation was performed with ease, after the vocal cords were sprayed with 5% hexylcaine topical solution. Throughout the procedure 100% oxygen was given. To insure that the patient would remain quiet during the first valve fracture 30 mg. of succinylcholine was given intravenously. The patient was able to open her eyes on command after each attempt at valvular fracture, which was performed three times.

At the termination of the operation, two hours later, she was given appropriate posthypnotic suggestions with regard to comfort, relaxation, and the ability to breathe deeply and cough adequately. She was then asked to remove the endotracheal tube herself, which she did. She was then taken to the recovery room and asked to awaken, and she responded immediately. This patient made an uneventful recovery, requiring no narcotic drugs postoperatively.

Hypnoanesthesia.—The operation of mitral commissurotomy has, until now, never been performed with the patient entirely under hypnosis. The case I am about to describe is the first mitral commissurotomy on record in which hypnosis was the sole means of anesthesia.

Case 8.—A 42-year-old woman entered the hospital for mitral commissurotomy. Two years prior to this she had undergone an operation for multiple vein ligation and stripping under hypnoanalgesia, which I reported previously.[15] Because of the successful result obtained in the former operation she was sufficiently motivated to have the mitral commissurotomy performed under hypnosis. She was seen three days prior to surgery and responded extremely well to hypnotic suggestions. During the three-day conditioning period she was able to reach a deep trance level and achieve complete anesthesia of the chest wall. Because of her response I felt encouraged to attempt the procedure entirely under hypnosis. The night prior to surgery she was given no sedative drugs and slept well all night in response to posthypnotic suggestion. The morning of surgery, at 7 a. m., she was rehypnotized in her room and brought to the operating room in a deep hypnotic trance. She was given oxygen to breathe for 10 minutes, during which time an intravenous infusion of 5% dextrose in water was begun. Endotracheal intubation was performed, after the vocal cords were sprayed with

5% hexylcaine solution. The operation began at 7:45 a. m. Throughout the procedure the patient was able to open and close her eyes in response to command. She tolerated the endotracheal tube without any difficulty. Throughout the entire operative procedure 100% oxygen was administered. At one point during the operation, when it was necessary to facilitate the surgery by making the operative field quieter, 30 mg. of succinylcholine was given by intravenous drip. This was the only drug which the patient received during the procedure. Succinylcholine is a muscle relaxant with no analgesic or anesthetic effect. When the operation was completed, at 10 a. m., the patient was awakened gradually by being brought out of the hypnotic trance. Prior to awakening she was given posthypnotic suggestions relative to comfort, deep breathing, and ease of coughing and was told that she would be asked to remove the endotracheal tube by herself. She was then asked to awaken. With the endotracheal tube still in situ the patient was asked to shake my hand and to squeeze it tightly. She responded readily. She was informed that the operation had been completed and was performed successfully under hypnosis. After aspiration (by suction) of the mucus from the mouth, pharynx, and trachea the patient was asked to remove the endotracheal tube and hand it to me. She responded readily. She was then asked to wet her lips and to stick out her tongue, which she likewise was able to do. She was taken to the recovery room, wide awake and alert, but with total operative amnesia. During the postoperative period, she required no narcotics or sedative drugs. She made a rapid and splendid postoperative recovery.

Comment

What is the advantage of having the patient remove her own endotracheal tube? This informs us that the patient is completely awake and capable of a coordinated muscular effort, the performance of which requires a high level of integration. It also indicates that no serious cerebral embolic phenomena have occurred during surgery.

Although anesthesia by means of hypnosis cannot be induced in every patient as surely as chemical anesthesia, and therefore will never replace or universally substitute for chemical anesthetic agents, there is much to be gained by the use of hypnosis in suitable cases. Hypnosis has a great deal to offer the anesthesiologist in the proper management of preoperative fear, anxiety, and tension. In cardiac surgery it enhances the patient's ability to withstand the surgical and anesthetic procedures. The use of posthypnotic suggestion will also aid the patient in his postanesthetic and postoperative recovery.

Hypnosis is not a substitute for proper medical therapy or good surgical handling of the patient. What is needed for the sick patient is what Meyer has called "warmth without heat, light without fire, and air without drafts."[16] The calm, quiet, kind reassurance which can be induced with hypnotic techniques may give the patient an inner peace and fortitude that cannot be equaled by tranquilizing drugs. It offers the patient a warm and steady hand which can help guide him safely through the anticipated surgical and anesthetic experience.

Conclusions

Hypnosis can be an invaluable aid in the anesthetic management of the patient undergoing cardiac surgery. Its effective applications include the allaying of fear, the quieting of anxiety, reduction of the total anesthetic dose, the production of analgesia and anesthesia, a safe and amnesic surgical journey, and, as a result of posthypnotic suggestion, a pleasant postoperative recovery and a greater motivation toward getting well.

Hypnoanalgesia was successfully employed in the closure of interatrial septal defects in three children and in mitral commissurotomy in four adults. The first mitral commissurotomy performed with hypnosis as the sole means of anesthesia has also been documented.

ADDICTION, ADDICTING DRUGS, AND THE ANESTHESIOLOGIST

Edward R. Bloomquist, M.D., Glendale, Calif.

Patients who are addicted to narcotics pose a special problem to the anesthesiologist because they sometimes require unusually large doses of premedicants and anesthetics, manifest withdrawal symptoms while in the hospital, develop complications (e. g., tetanus and hepatitis) from previous infections, or act in devious ways to conceal or satisfy their need for narcotics. Any drug with analgesic, relaxant, or euphoric properties is potentially addicting. This applies to meprobamate as well as to meperidine. It also applies to volatile anesthetics like nitrous oxide and fluothane. Anesthesiologists are advised to refrain from sampling anesthetic drugs for any reason. When a physician uses potentially addicting drugs to relieve pain he exercises a sacred right, but he also assumes tremendous responsibilities.

At first glance anesthesiology may seem far removed from addiction. Actually, anesthesiologists have a close professional and, occasionally, personal interest in this subject. Anesthesiology is unique in that all patients benefiting from this service receive a combination of drugs which possess a high addiction potential.

To use these drugs intelligently one must have an extensive background in pharmacology, chemistry, and physiology. This education is a prerequisite for the safe administration of currently available anesthetics and enables the anesthesiologist to make decisions which affect not only health but life itself. It further contributes to proper management of unusual problems which may arise. An example of this is the situation which occurs when a narcotics addict becomes a surgical risk.

While narcotics addiction is more likely to be seen by physicians practicing in heavily populated areas, it does not follow that doctors in other areas can dismiss from their minds the possibility of having an addict as a patient. Americans are on the move, and as this continual relocation occurs addicts are scattered throughout the country and inevitably thrown into contact with potential addicts. This type of association is one of the prime factors in the spread of addiction.

Four states currently contain 77% of known addicts: New York (45%), Illinois (14%), California (13%), and Michigan (5%). Following at a distance with a less intensive problem are Texas, the District of Columbia, Missouri, Ohio, New Jersey, and Pennsylvania.

According to latest figures 59% of addicts are Negro, 27% Americans of European stock, 7% Puerto Rican, 5% Mexican, and 2% miscellaneous.[1] Sociological factors apparently play a major role in addiction among Negroes, whereas the prime factor among Caucasians seems to be personality disturbance. Although no single factor is universally accepted as the cause of addiction, the problem is generally recognized as a sad reflection of the critically unbalanced social, moral, and cultural state of our present civilization. As such, it is important to all of us.

No one can quote, without debate, a figure which represents the exact number of addicts in America. Although this number may not be known, enough are present to create a problem. And since addicts periodically need surgery, the management of their addiction and its relationship to anesthetic and analgesic requirements is a matter of interest to all anesthetists.

Recognition of Addiction

Statistical Picture.—The general statistical picture of the addict is indicative but not always specifically applicable. Of currently known addicts 60% are between the ages of 21 and 30 years. Only 12% are aged under 21. Seventy-eight per cent are male. Diacetylmorphine (heroin) is the preferred drug among addicts outside the medical profession, whereas the latter prefer meperidine (Demerol) hydrochloride. Among diacetylmorphine addicts over 90% begin the treadmill through the use of marijuana.[1]

One cannot describe a satisfactory personality picture of the addict, because it will vary with the circumstances under which he is seen. Psychiatrists and social workers often find him quite likable, for the addict usually responds to genuine personal interest. Law enforcement authorities, on the other hand, see an entirely different picture.

It is purely a matter of conjecture which face the addict will show when confronted with an emergency surgical situation where, at best, he faces a controlled withdrawal from narcotics. Successful management of the addict under these circumstances depends to a great extent on the attending

Read in the Symposium on Common Problems before the Joint Meeting of the Section on Anesthesiology and the Section on Nervous and Mental Diseases at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 11, 1959.

physician's awareness of the problem and its ramifications and the tact and sympathy with which he faces the situation.

Physical Examination.—Physical examination may reveal many of the telltale age-old signs of narcotics addiction. Pinpoint pupils and needle marks on the skin overlying accessible veins, accompanied by varying amounts of phlebitis, cellulitis, scarring, and venous occlusion, may serve as pathognomonic signs. The antecubital area, frequently the one preferred for injections, may be obscured by a tattoo, obtained in an effort to minimize evidence. The addict, however, is as aware of the significance of needle marks as are authorities and often uses veins other than the antecubital. Some of these veins are between the fingers and toes, behind the knees, on the dorsal aspect of the hand or foot, and, rarely, the external jugular.[2]

Withdrawal symptoms also serve in diagnosis if withdrawal is imminent. Sneezing, anxiety, yawning, goose flesh, nausea, and vomiting are most often seen.

Diagnostic Test.—The nalorphine (Nalline) hydrochloride test, with the antagonist administered in 3-mg. doses under a controlled clinical situation, causes the pupils of persons who have recently received narcotics to dilate. There are many legal and medical problems associated with this examination, however, and interested physicians are advised to acquaint themselves thoroughly with the problems that may occur before performing this test.[3]

Attitude.—Friendly interest, reassurance, the ability to withstand verbal assaults without undue remonstrance, and a patient explanation of why it is so important to obtain a complete history will frequently encourage cooperation and make the diagnosis easier.

It is suggested that anesthesiologists include the question, "To what drugs have you been addicted?" to their routine questions, inasmuch as the list of drugs with potentially addicting properties is constantly increasing. The question, "Have you ever been addicted to—" is a rather poor one, for it permits the patient simply to avoid the issue with a negative response, the doctor often being none the wiser.

Special Considerations

If a history of addiction is obtained, several factors should be considered. If the addiction is past history, the use of narcotics should be avoided if it is clinically permissible. The judicious use of barbiturates, tranquilizers, and scopolamine in such cases usually provides the desired pharmacological effect, and the hazard of readdiction is avoided. For, while it is not true that "once an addict, always an addict," it can be stated with a degree of accuracy that once an addict, always a potential addict.

If narcotics are required to control pain, they should be used in adequate amounts. The patient must have an individually tailored program, however, and attenuation of the dosage must be attempted as soon as possible. A most useful adjunct in controlling pain and apprehension, so often overlooked in the increased tempo of modern medicine, is the frequent visiting of the patient by his physicians. Sedatives and analgesics are useful weapons in the fight against pain and anxiety, but they are poor substitutes for personal attention.

If the patient is currently addicted, surgery should, if possible, be postponed until withdrawal is accomplished. Management is much easier if the addict is not concerned about potential withdrawal symptoms. More important, tolerance is reduced so pain can be controlled with reasonable quantities of analgesics.

Tolerance varies remarkably with the individual. A case in point is that of a young man who recently asked officers of the Los Angeles narcotics squad to arrange for treatment of his addiction. His tolerance was so great that he could not keep ahead of withdrawal symptoms, particularly since he depended on theft as a source of supply. At the time seen, he was using 20 tablets of 1/16 grain (0.004 Gm.) of dihydromorphinone (Dilaudid) hydrochloride intravenously every four hours.[4]

If the patient is addicted and surgery cannot be postponed, narcotics should be reasonably administered to provide comfort before and after surgery. The patient's addiction, however, does not provide a reason to be careless in administering drugs. Furthermore, surgical convalescence is not a contraindication to withdrawal of narcotics, when the patient's condition permits. Only careful observation can make withdrawal under these circumstances a success, however, for one must constantly try to differentiate between somatic pain and psychological distress or misrepresented pain; the addict, particularly if personnel are unaccustomed to working with addiction, can frequently manipulate the situation to his advantage.

When an addicted person needs emergency surgery, the following factors should be taken into consideration. 1. It is unlikely that adequate veins will be available at the time of the operation. Because of this, cut-downs should be planned prior to surgery. 2. Administration of narcotics must be kept to a minimum and terminated as quickly as possible. This plan should be outlined from the first, so the addict will have no misinterpretation of what can be expected. 3. Some addicts require large amounts of intravenously administered barbiturates to obtain the full effect. Youth may be one of the factors that contribute to this increased tolerance. Not infrequently the patient will also have a history of alcoholism.[5] 4. Individual response to preanesthetic and postanesthetic sedatives and analgesics is unpredictable, and optimum medication cannot always be achieved. As a working example, the U. S. Public Health Service Hospital at Lexington, Ky., gives the average adult addict morphine sulfate, 10 mg.; scopolamine, 0.6 mg.; and pentobarbital, 100-200 mg., for premedication. Chlorpromazine, 25 mg., is added as indicated. 5. Addicts may require more postoperative analgesia initially than nonaddicts, a factor which makes close observation essential. 6. Some physicians who manage addicts as surgical patients feel that they do not tolerate stress too well. Until future studies clarify this point, it is well to anticipate possible adrenal cortical insufficiency during surgery.[6] 7. If facilities are available where management of addiction is common practice, it is well to consider sending the patient to these facilities for both withdrawal and definitive care.

In recent years a newly recognized syndrome of narcotics addiction and withdrawal in babies born of pregnant women addicted to diacetylmorphine has been described. It is important that physicians be aware of this possibility, for improper treatment or lack of treatment may result in the death of the newborn infant. When the umbilical cord is clamped the child is forthwith deprived of his narcotics supply. Unless quickly recognized this deprivation may be fatal, particularly if the mother has developed a high tolerance and/or has had a recent injection of narcotics.

Schneck[7] has outlined several symptoms which may be incorrectly interpreted unless the attending physician is aware of this syndrome. The babies are restless and irritable and emit a relatively continuous, high-pitched, piercing scream. As is true of adult addicts in withdrawal the babies yawn, are sleepy, sneeze, sweat, and have stuffy noses and copious secretions. Anorexia, vomiting, and diarrhea are also observed, and, more important, convulsions. The latter symptom is often mistaken for brain damage, and valuable time is lost waiting for a neurological evaluation.

In the meantime the combination of vomiting, increased mucus, and the usual problems that occur with the respiratory physiology and anatomy of the newborn infant may lead to sudden respiratory failure.

An additional hazard exists if the mother has been given narcotics without the physician's awareness of her addiction, and the resulting symptoms in the child are interpreted as narcotic depression. For if nalorphine is given under these circumstances, the baby may die.

The death rate thus far has been quite high among addicted newborn infants. Treatment, if instituted early, may reduce this mortality. Suggested measures include aspiration, oxygen as indicated, and administration of methadone, tranquilizers, or both, in diminishing amounts.

The situation can be unpleasant. Few, if any, addicted mothers seek prenatal care, arriving at the last minute because of necessity. They may exhibit signs of preeclampsia, infected veins, hepatitis from contaminated needles, and, because many resort to prostitution, venereal disease. Cooperation may be minimal, with a number leaving the hospital against consent to avoid withdrawal symptoms. In those who stay it is often difficult to manage withdrawal because of narcotics smuggled to the patient by friends.[8]

Several complications caused by group use of contaminated needles may occur in addicts and subsequently affect the choice and administration of anesthesia. Among those reported thus far are malaria, septicemia, cellulitis, phlebitis, venereal disease, bacterial and mycotic endocarditis, tetanus, and hepatitis.[9] The latter two complications are most frequently seen.

The occurrence of tetanus in narcotic addicts was first reported in an editorial in the *Lancet* in 1876. Since then several series of case study reports have appeared. One of the largest is that of Levinson and co-workers,[10] who surveyed 22 cases of tetanus, 12 of which were in diacetylmorphine addicts. Addicted tetanus victims were found to be younger than nonaddicts in this series (75% of addicts were between 20 and 30 years of age, as contrasted to 60% of nonaddicts who were over the age of 40). Of the addicts 75% were female. All were Negroes. All addicts lapsed into coma, with higher temperatures, much sooner than nonaddicts (12-36 hours). Copious secretions complicated an already difficult situation. Most nonaddicts complained of trismus as the first symptom, but addicts initially noted a stiff neck or back, or both.

Although treated in the same manner a 100% mortality prevailed among addicts, whereas only 40% of nonaddicts died. This was attributed to delayed diagnosis because of the addicts' reluctance to seek hospitalization until too late.

Hepatitis constitutes a general problem, since certain persons with or without evidence of hepatic disease may be carriers for several years. Thus, the addict may well be an important epidemiologic factor in spreading this disease. A series of five cases acquired from the same contaminated needle and medicine dropper, in addicts ranging in age from 15 to 24 years, was recently reported.[11] And, interestingly, Havens has commented on the history of an 18-year-old addict who suffered three separate attacks of self-limited jaundice, caused by immunologically different virus, within a period of two years.[12] In suspicious cases, the presence of hepatitis may be an assisting factor in establishing a diagnosis of narcotics addiction.

Prevention

Much has been said about the treatment of addiction and its complications. More worthwhile, however, is a discussion of the prevention of addiction.

When a physician decides to use potentially addicting drugs to relieve pain, he employs a sacred and marvelous right. He also assumes tremendous responsibilities. It is impressive that, while 80% of addicts admitted to the U. S. Public Health Hospital in Lexington, Ky., in 1957, were social addicts (persons receiving drugs from illicit sources), 20% were medical addicts—persons who became addicted while taking drugs for therapeutic purposes and who depended on physicians for their source of supply. The opiate principally involved in the latter cases was meperidine.[13]

Meperidine is also the preferred narcotic among addicted members of the medical profession. Easily acquired and simply given, it produces a relaxation which relieves tension and, for a time, the problems of a busy practice or disturbed personality seem to disappear.

Significantly, this drug went through a long period of sales promotion which declared it free from addicting properties. It was hoped that this type of promotion would never mislead the profession again, for it is now recognized that any drug with analgesic, relaxant, or euphoric properties is potentially addicting. But not long ago a similar unfortunate campaign promoted meprobamate (Miltown, Equanil) as a safe psychological cure-all. Too late some are finding that it, too, is addicting.

Recently a doctor was sued for $301,000. The charge: A 36-year-old woman had been addicted to narcotics by her physician. One of the factors which irritated her was that he allegedly was using part of the narcotics prescribed for her for his own purposes. The case was settled out of court.

Experiences with varying phases of justice have created a growing tendency among contemporary American physicians to practice medicine with one eye focused on the patient and the other on his attorney. This antediluvian situation has caused far more harm than good. One important reaction, sometimes fortunate, sometimes not, has arisen from it—doctors have developed an extreme sense of caution. In narcotics addiction this has been an asset, for caution is the watchword in its prevention.

Responsibility of Physician

When a physician elects to use narcotics as a part of his armamentarium, he should review certain facts.

Does the patient really need narcotics, or would personal attention, discussion, encouragement, and the use of physical therapy or regional anesthesia be a better choice for subduing pain or allaying anxiety? Far too often one hears an attending physician comment to his resident, "Give him my routine orders for pain." There are no routine orders for pain. Nor is there any excuse for the standing order, "narcotic X q 3-4 hours p. r. n. pain," unless this statement is evaluated daily as the changing needs of the patient are considered.

Analgesics should be chosen to fit the particular case. Physical addiction can usually be accomplished if a short-acting narcotic is given at frequent intervals over a two-week to three-week period. For this reason meperidine would seldom be indicated as a postsurgical analgesic, if analgesia must be prolonged. Levorphanol (Levo-Dromoran) tartrate, methadone, and similar narcotics which are long-acting, available in orally given preparations, and do not permit tolerance to build up so rapidly are preferable in such cases to meperidine or morphine.

Switching narcotics in an attempt to avoid or decrease addiction is not usually successful. Narcotics have a cross-tolerance, and development of tolerance to one results in increased tolerance to all.

Addictive potentials of "mild" analgesics should not be underestimated. One frequently finds the statement in medical literature that codeine addiction seldom exists. It is more accurate to state that it is seldom recognized. For, by the time a person who began his narcotics addiction with codeine is apprehended, he has usually changed to something stronger. Addicted physicians with whom I have talked, who have had personal opportunity to compare the detrimental effects of both codeine and meperidine, have exhibited far greater respect for the problems inherent in codeine withdrawal than for those experienced with meperidine.

Because of constant use in their profession, anesthesiologists find it simple to acquire narcotics (legally, or, for a time, illegally). This fact merits mentioning another precaution. Except under circumstances of strict emergency, narcotics should not be administered to one's self or family. If this rule is not observed, and the proper situation exists when it is broken, disaster can occur.

If a patient becomes addicted, physiologically or psychologically, or both, to a narcotic while in the hospital, it is the attending physician's responsibility to try to effect withdrawal before releasing the patient. If he is unsuccessful, although not required by law to do so, he is wise if he encourages the patient and his family to place the addict in an appropriate institution that can adequately handle withdrawal problems.

Hazards for Anesthesiologists

For anesthesiologists, there is another point of prophylaxis that should be mentioned. It is interesting to note that the one feature of gas anesthetics immediately accepted, even to the point of ignoring their potential for relieving pain, was the ability of ether and nitrous oxide to cause euphoria. When Crawford W. Long was a medical student, he frankly admitted inhaling ether for its exhilarating properties. And it became routine for several young men, and frequently ladies, of the town to hold ether sprees in Long's office two or three times a week.[14]

Sniffing gases for psychological effects has not disappeared with the passing of time. In 1957 the warden of San Quentin prison expressed concern because inmates had begun the practice of inhaling solvent fumes as a substitute for drugs or alcohol. Since available solvents were either gasoline, paint thinner, paint remover, or carbon tetrachloride, the physical damage to the sniffer was potentially great. A third of the cases brought before the prison's disciplinary committee that year were for infractions of the rule prohibiting this practice.

Foolhardy individuals, particularly emotionally immature persons, outside prison society not infrequently perform similar acts. The anesthesiologist who acts as a consultant in cases of poisoning will inevitably run across cases of fatal or near-fatal poisoning from inhaling solvents or the ingestion of "social" alcohol substitutes such as antifreeze.

Anesthetic gases still hold a fascination for some, although this problem is not one that usually affects the general public. Within the profession, however, particularly among anesthetists and dentists, they remain an easily accessible pharmacological escape for those who enjoy synthetic release, be it ever so brief, from tension and anxiety.

Many institutions where anesthesiology is taught permit the not uncommon practice of smelling gas mixtures to check both concentration and content. For the most part, this is an innocuous procedure. For some, however, it may be an unfortunate introduction to the euphoric effects of these gases. At the end of a two-year or three-year residency, particularly since most doctors seem to give little consideration one way or another to the practice, a habit leading to addiction may be produced in susceptible persons. At Children's Hospital in Los Angeles it is stressed that no one, resident or chief, should develop the habit of smelling anesthetic mixtures. For it is felt that to those persons who may be termed "addiction-prone" the ready access to these gases presents a real hazard, if the habit of smelling anesthetics is encouraged.[15] Pursuing this subject further, it was found that other anesthesiologists had had experiences with anesthetic gas addicts. Some of the anesthetists known to have been involved have at one time been leaders in the field.

Gas sniffers, like narcotics addicts, may be "chippy" (sporadic) or chronic users. Nitrous oxide is often used sporadically because its effects quickly disappear. A case in point is that of a dentist who, in time, became perpetually late for his next appointment because he closeted himself with his gas inhaler between patients for a brief escape from reality.

Cyclopropane sniffers present more of a hazard, for, if they pause during an anesthetic procedure to engage in their habit, they may become incapacitated at a moment when alertness may mean the difference between life and death. One person was known to go so far as to take a tank of cyclopropane gas home with him at night and use it to promote sleep.

Ether and chloroform have also been useful to persons seeking this type of emotional release. Trichlorethylene has its advocates, Derobert having reported a case in 1956 of a death which occurred during addictive inhalation of this gas.[16]

Apart from, but related to, the sniffers is the person who becomes addicted to the intravenous administration of barbiturates. An unusual case history was obtained of a physician who administered thiopental (Pentothal) to himself by intravenous drip, managing somehow to shut it off when the desired effect was obtained without slipping into permanent oblivion.

Recently a London anesthetist was discovered euphorically inhaling a mixture of oxygen, nitrous oxide, and fluothane. Unfortunately, he chose to do this at a time when he was administering an anesthetic to a 2½-year-old child undergoing a herniorrhaphy. The child died as a result of his negligence.

At his trial, where he was found guilty and sentenced to prison, he admitted he had been addicted to the inhalation of volatile anesthetics for seven years. His colleagues belatedly testified that they had seen him inhaling gases from the anesthetic machine before and during surgery on previous occasions.[17]

Almost anything producing the proper effect can, it seems, cause addiction. In 1957 U. S. Navy physicians O'Driscoll and Lindley [18] reported the case of a narcotics addict who had switched to intravenous administration of tripelennamine (Pyribenzamine) hydrochloride. The addict was aware of some 10 associates involved with the same drug.

On checking with the manufacturers the doctors received information that this drug was being used in a similar manner in Detroit. Termed "blue velvet" by its users, it produced an effect less dramatic than but somewhat similar to that of marijuana.

Admittedly, addiction to anesthetic drugs is uncommon. The fact that it does occur, however, suggests that everyone who uses these substances may find it advantageous to refrain from sampling them for any reason. It appears that the position of those who feel residents in training should be discouraged from this habit is fortified.

Summary

Extensive training in the pharmacology of addicting drugs and their constant clinical employment places the anesthesiologist in a vital position when narcotics addicts require surgery. Before treating the addicted patient it is wise to obtain a complete history of the individual problem, so that this history, combined with an awareness of the complications unique to users of addicting drugs, may be used to manage the case in as satisfactory a method as possible.

As resuscitation consultants, anesthesiologists should also be aware of the bizarre habits of addicts which make diagnosis difficult when either resuscitation or anesthesia is indicated.

Constant use of drugs with a high addiction potential should make anesthesiologists careful in personal compliance with narcotics regulations, constantly being aware that routinely handled drugs, including anesthetic gases, are an ever-present threat to susceptible persons.

MEDICAL, SOCIAL, AND LEGAL ASPECTS OF SUICIDE

Robert D. Dripps, M.D., Maurice E. Linden, M.D., Harold H. Morris, M.D.
and
William A. Phillips, M.D., Philadelphia

The increased frequency of suicide among the various causes of death makes it too important to ignore as a medical problem. The depressions that lead to suicide are not prevented by threats of either secular or eternal punishment; often they are the results of organic brain disease, occupational injuries, nutritional deficiencies, or intoxications. Popular attitudes, present laws, and the policies of insurance companies also work unjustified hardships on survivors, contribute little toward prevention, and impede the collection of accurate data. Persons who attempt suicide often receive inadequate treatment. During the emergency stage an anesthesiologist can be most helpful. Later the services of a psychiatrist are essential, his chief challenge being to estimate the likelihood of a second suicidal effort. Society should soon be sufficiently mature to deal with this problem more logically than it has in the past.

The problems of which suicide is a manifestation are greater in frequency and consequence than the interest in this field of study would indicate. Suicide is the 11th leading cause of death in the United States. Studies in Philadelphia show that, for every successful suicide reaching the medical examiner's office, at least five additional attempted suicides become matters of police action. In addition, an undisclosed number of attempted suicides, not so classified, are treated under other diagnostic labels in general hospitals. Medical reasoning also concludes that at least some deaths listed as due to accidents have been instances of suicide. Table 1 shows the 11 leading causes of death in the United States in 1956, the last year for which complete data are available.

It is seen that suicide accounts for nearly as many deaths as cirrhosis of the liver, or all congenital malformations combined. As a killer, suicide is

two-thirds as important as diabetes mellitus and more than half as significant as generalized arteriosclerosis. Organized national efforts are being made to combat tuberculosis, poliomyelitis, nephritis and nephrosis, muscular dystrophy, multiple sclerosis, epilepsy, arthritis, alcoholism, and other conditions. Yet deaths due to suicide outnumber those due to tuberculosis and those due to the rest of the foregoing conditions combined (table 2).

TABLE 1.—*Number of Deaths and Death Rates for Eleven Leading Causes of Death in 1956 and Estimates for 1958 in the United States**

	International Classification†	Cause of Death	Deaths in 1956		Estimated Deaths in 1958	
			No.	Rate‡	In Sample§	Rate
1	410-443	Diseases of heart	602,995	360.5	629,720	365.8
2	140-205	Malignant neoplasms	247,357	147.9	251,670	146.2

† World Health Organization: Manual of International Statistical Classification of Diseases, Injuries, and Causes of Death, Sixth Revision, Geneva, 1958.

‡ Death rate per 100,000 estimated population.

§ Figures given were the 10% mortality sample for January-December, 1958, projected to a 100% base.

Successful suicides account for 17,000 deaths per year in the United States, an incidence of approximately 10 per 100,000 population. The suicide rate rises during national catastrophes and eras of widespread distress, the highest incidence of suicide in the United States occurring in 1932 when there were 20,646 deaths due to this cause. In addition, there was a high incidence throughout the years of the financial depression, 1929 to 1940. A considerable reduction in suicides occurred during the years of World War II, to a low of 13,231 suicidal deaths in 1944.

Studies on attempted suicide are lacking or of small scope, owing to the fact that this is a difficult field in which to gather statistics. Data on successful suicides afford a basis on which to develop estimates. The following information has been gained from a study of suicides in Philadelphia, completed for 1955.[1] This study revealed that the highest rate occurred in persons 75 years of age and over (table 3). Police records disclose a much higher incidence of attempted suicide among youngsters under the age of 17 years than is generally realized. Adolescence, a period of life normally fraught with turmoil and immature psychological organization, would also seem to be a period significant to the physician in terms of drives toward self-mutilation and self-destruction. The highest suicide rate in Philadelphia occurred in the central city district which tends, as in most cities, to include cheap hotels, rooming houses, and "skid row." Studies in large cities generally agree that suicide is more prevalent in socially disorganized parts of the city.[2] The Philadelphia study, however, did not support the conclusion reached by other surveys that the suicide rate decreases in direct proportion with the distance from the center of a city.

The Philadelphia survey demonstrated significant sex and race differences among suicides, the incidence being greater than two to one among the whites, with white males predominating four to one over white females, and nonwhite males six to one over nonwhite females. The study further revealed that approximately half of the suicides occurred among married people. About 20% were single, 14% divorced or separated, and the rest widowed. About one-third of successful suicides were persons with regular employment; about one-fourth were unemployed; approximately one-eighth were retired; and in the remaining cases the information was unobtainable.

In the majority of suicidal attempts prior to death the victim was claimed to be suffering from some form of illness, either physical or mental. A greater number of suicides have complained of chronic physical illnesses than of mental disorders, although mental depressions are high on the list of complaints. The mental condition of suicides, as obtained from records and interviews with members of families and other relatives, friends, and neighbors, shows a high incidence of "nervousness" or "mood and behavioral changes" (table 4).

TABLE 2.—*Deaths from Selected Causes in the United States in 1956**

Cause of Death	Deaths, No.
Suicide and self-inflicted injury	16,720
Tuberculosis (respiratory 12,978, other 1,083)	14,061
Epilepsy	2,098
Alcoholism	2,066
Deliveries and complications of pregnancy, childhood, and puerperium	1,702
Arthritis and rheumatism (except rheumatic fever, with 1,033 deaths)	1,557
Multiple sclerosis	1,448
Nephritis and edema, including nephrosis	1,140
Poliomyelitis (acute 566; late effects 139)	705
Muscular dystrophy	484

* Vital Statistics of U. S. 1956, vol. II., Mortality Data, National Office of Vital Statistics, U. S. Department of Health, Education, and Welfare, U. S. Government Printing Office, 1958.

Alcoholism appears to play an important part in the decision to attempt suicide and was present in at least 10% of cases studied. It is believed that alcoholism has a considerably greater incidence among suicides than in the general population. Of importance to the medical profession is the finding in the Philadelphia survey that 77% of successful suicides have been under medical care. Of the entire group studied for one year 13% were reported to have threatened suicide. An additional 9% had made one or more previous attempts. In 3% of the cases it was found that both previous attempts and threats were reported. Researchers in this field agree that the 25% incidence of threats or attempts, as noted above, is probably an underestimation.

TABLE 3.—*Suicide Rate per 100,000 Population, by Age, Sex, and Race, in Philadelphia, 1951-1955**

	White		Nonwhite		
Age Group, Yr.	M	F	M	F	Total
75 and over	47.1	7.7	10.8	...	21.7
65-74	35.2	9.2	20.7	3.0	19.9
55-64	35.8	7.4	14.7	1.6	19.7
45-54	16.5	6.6	4.2	1.7	9.9
35-44	9.4	6.2	10.4	1.8	7.3
25-34	6.7	2.8	13.1	1.0	6.0
15-24	2.9	0.7	1.6	1.9	1.8
Total†	12.1	4.0	6.6	1.2	7.2

* Data from Tuckman and Lavell.[1] Rates calculated by dividing total number of suicides in each age group in five-year period by appropriate 1950 census figures, multiplied by five.

† Does not take into account the age-specific rate for each group.

The majority of suicidal efforts take place in the home. This is especially true of housewives. About 20% occur in public places. The Philadelphia study, which was interested in many facets of the personalities of would-be suicides, found that approximately 25% leave suicide notes.

The method applied in successful suicide varies from one locality to another, depending on the availability of various kinds of lethal instruments. One practitioner has reported to us that farmers and rural inhabitants, who are apt to possess firearms, are likely to use this method. Suicide by hanging is more common in areas having a large number of homes with basements. Death by jumping is common where there are high bridges and rapid trains. Suicide by illuminating gas was commoner in days when gas was more plentifully distributed and contained larger fractions of poisonous substances. In successful suicides in the Philadelphia study the methods most commonly employed, in the order of incidence, were as follows: hanging; use of firearms; ingestion of some form of medicament, drug, or poison; inhalation of gas or carbon monoxide; and jumping from high places or in front of rapidly moving vehicles. Cutting, stabbing, and drowning combined accounted for about 8% of all the methods.

Dependable statistics are not available regarding the methods employed in the attempted suicides. Medical experience and the examination of police reports suggest that the taking of barbiturates and other sedatives, as well as cutting and slashing, are the methods most commonly employed in attempted suicides. In many instances attempted suicides would have been successful had it not been for timely intervention by a relative, friend, or neighbor.

Emergency Treatment

The person attempting suicide may be saved by the intervention of the one who first comes on him. Lay persons and physicians as well must act promptly and with intelligence. Therapy for attempted suicide by trauma, e. g., firearms, jumping, or cutting, is usually first-aid and surgical. Attempted suicide with use of gas or drugs involves immediate support of respiration in many instances. The anoxia of inadequate alveolar ventilation, with its threat to brain function, can be reduced by artificial ventilation promptly and intelligently performed. Mouth-to-mouth or mouth-to-nose techniques have been shown to be superior to "manual" methods, so far as the volume of ventilation provided is concerned.[3] Adequate ventilation by this or any other means must be maintained until the patient is admitted to a hospital. The patient should be sent directly to a recovery room and placed in charge of an anesthesiologist. He should not be delayed in the receiving ward, where personnel are less experienced in the therapy required.

Hospital Treatment.—Supportive therapy has greatly reduced the mortality of patients in coma from poisoning. The details of a proper program have been described elsewhere by a number of authors.[4] Essentially it consists of maintenance of alveolar ventilation and tissue perfusion, prevention of infection, and protection of skin and mucosa from injury. Oxygenation and removal of carbon dioxide demand a patent airway and may require tracheal intubation and bronchoscopic aspiration, tracheostomy, or both. Provision of an adequate tidal volume of respiration may require use of a mechanical ventilator. Oxygen need be added only if the saturation of hemoglobin is subnormal, or if arterial oxygen tension is below 100 mm. Hg.

Tissue perfusion is supported by maintenance of a normal blood pressure through intravenous infusion of fluids and use of pressor drugs if indicated.

TABLE 4.—*Reported Mental Condition of Suicides, by Race and Sex (in Percentages), in Philadelphia, 1951-1955**

	White		Nonwhite		
Mental Condition	M (n=496)	F (n=175)	M (n=59)	F (n=12)	Total (n=742)
Presumably normal	4	3	0	0	4
Nervous or mental condition	27	55	19	33	33
Mood or behavioral changes	39	29	24	17	35
Not stated	30	13	57	50	28

* Data from Tuckman and Lavell.[1]

Electrolyte determinations and measurements of urine volume and specific gravity will aid in determining whether sodium or chloride should be added to the perfusate. A catheter left in the urinary bladder assists in this. Antibiotic therapy, turning the patient hourly, pummeling the chest wall energetically, and aspiration of respiratory tract secretions minimize the danger of pulmonary infection. The heels and knees should be padded to prevent pressure sores. The eyelids must be kept shut to avoid corneal damage. A continuous record of vital signs is essential.

With these measures established one can consider three other types of treatment. Nonconvulsive electric stimulation of the central nervous system offers little. Use of analeptic agents remains controversial, with our vote recorded against their use except in severe depression. The newest substance, bemegride (Megimide), remains to be evaluated. It may increase respiration but has not yet been shown to shorten the duration of coma after ingestion of barbiturates. Use of the artificial kidney to remove drugs which are not bound to protein, in markedly depressed patients, deserves serious consideration.

Role of the Psychiatrist

A psychiatrist should assume major responsibility for the patient as soon as emergency treatment has become effective. The development of a positive relationship between patient and physician is facilitated if the physician is present as the patient awakens. Also of importance is the fact that, during this twilight state, significant feelings may be revealed which may be suppressed later on.

The psychiatrist's chief challenge is to estimate the likelihood of a second suicidal effort. An adequate history contributes greatly to the accuracy of such an estimate. Indications of a drive toward suicide are various combinations of the following factors: (1) a history of previous suicidal attempts; (2) hints from the patient's conversation or actions that he has been contemplating suicide (in most cases the patient gives some clear indication of his intent prior to the act); (3) a story of severe depression with insomnia, anorexia, loss of interest, and self-recrimination for a period immediately preceding the attempt, or a history of such depressive episodes in the past; (4) depression in a successful, driving, conscientious, somewhat compulsive person between the ages of 45 and 65 years; (5) a history of a period of well-being, overactivity, poor judgment, and perhaps some euphoria, as in a hypomanic reaction preceding the attempt; (6) lack of any obvious, external cause for the patient to be depressed or suicidal, suggesting the depression to be of an endogenous nature and hence likely to be more serious; and (7) a history of recent seeming emergence from a depressive or hypomanic attack. The most dangerous period, from the point of view of suicide, is when the patient seems to be recovering from such psychological illnesses and the physician's vigilance and concern relax.

One of the first tasks of the psychiatrist, then, is to obtain as accurate a history as possible, regarding both the circumstances surrounding the suicidal attempt and the patient's personality adjustment for several months previous. There are some personal factors which suggest that a serious suicidal attempt is less likely. Among these are a hysterical, dramatic, "acting-out" type of personality; membership in one of various ethnic groups in which the suicide rate is significantly lower than in others, such as Negro and southern European; a sudden emotional crisis during which the patient has acted impulsively, such as a lover's quarrel; an acute alcoholic or drug debauch; or a reaction to some current real problem, such as an illegitimate pregnancy or the death of a loved one.

Adequate care for the first several days after the attempt demands security screening in the patient's room and continuous observation by a psychiatrically trained nurse or attendant. Such constant observation should continue for at least two or three days. If facilities are not available in the hospital where the patient has received emergency treatment, he should be moved as soon as possible. This might be to the psychiatric unit of the general hospital where he was first treated, to a room or a ward on the psychiatric service of a municipal hospital, or to a psychiatric institution, depending on the medical resources of the community.

A Suicide Control Program.—In London and New York City a person fearing that he may attempt suicide can obtain immediate help day or night by contacting police or public health authorities. This is a start on what could prove to be an effective program for reducing suicide. The broad outline of such a suicide control program would include (1) the immediate reporting of suicides and attempts to responsible public health officials, (2) provision of immediate definitive medical attention, (3) recognition that such patients must not be left alone for the first few days after the attempt, and (4) transfer of such patients to a psychiatric division of a hospital for two or three days of observation. If a responsible adult relative refuses such a transfer he must be made to sign a statement to this effect, indicating awareness and acceptance of his responsibility.

Long-term follow-up plans would be the combined responsibility of the health department, and the medical staff and social service unit of the hospital. Threatened suicide without actual attempt could be reported to the same office, and a professional staff member could evaluate the nature of future steps. All reports would be strictly confidential.

Collection of Data.—The magnitude and parameters of the suicide problem require further definition. One approach to this is to improve the collection of data. There is no accepted formula for reporting information about suicides or attempted suicides. There is no listing in the standard nomenclature for the diagnosis of attempted suicide. In 2,750 of 3,049 counties in the United States coroners are not required to be medical men.

Therefore, in many cases of sudden death, no autopsy is performed. Many of the standard textbooks in forensic medicine have only scant references to the problem. The belief that reporting such cases would be a violation of doctor-patient confidence or that it stigmatizes the patient is frequently raised; these rationalizations seem to serve best the contention that our society does not really accept the suicide problem as a critical one. There is also the finding that only a small percentage of persons who attempt suicide eventually carry it out successfully, a viewpoint corroborated by Carr[5] and by Hendin.[6] It is important to determine if there are indeed two population groups, the "attempters" and the "doers." Improved data collection is urgently needed.

Suicide and the Law

The legal position toward suicide has been a reflection of the moral viewpoint adopted by our Western civilization. As Farrar[7] has indicated, the permissive attitude toward suicide of the pagan religions of antiquity was transformed into a severely restrictive and punitive one under the influence of early spokesmen of the Christian faith. Dogma was then converted into common law, and suicide became a crime punishable in Great Britain, for example, by the forfeiture of lands or chattels of the deceased (finally abolished in 1870). Although it is seldom enforced, the law in Britain still views attempted suicide as a crime punishable by two years' imprisonment. In most jurisdictions in the United States neither suicide nor attempted suicide is a criminal violation. We believe that it would be a backward step to make attempted suicide illegal once again. If nothing else, this would certainly interfere with data collection. Suicide is not a problem to be solved by law; rather, it demands the most thoughtful efforts of medical and social scientists.

There are aspects of liability which deserve comment. Most states treat the aiding or encouraging of suicide as a criminal act. This has particular importance for the doctor who frequently faces an incurably ill patient who pleads for an end to his suffering. Although the courts have tended to be lenient in ruling on cases such as these, the doctor has faced the censure of the medical profession.

In the problem of hospital liability, when an inpatient commits suicide, the most important criterion is whether or not the suicide could reasonably have been anticipated. Another factor would be whether reasonable precautions were taken to prevent the suicide. Hospitals may be held liable for employing persons who are given the responsibility of supervising a suicidal person and who are not competent to carry out this task. Essentially the same criteria apply to the individual physician who is treating the potentially suicidal patient. As soon as such a patient is seen, the physician should notify a responsible member of the family and should insist on hospitalization. Psychiatric referral should also be required, since the psychiatrist is more capable of evaluating a second attempt and thus of bearing the medicolegal responsibility.

In connection with an insurance company's responsibility to pay a claim on a decedent who commits suicide, in a case in which the policy declares its lack of liability in such cases, most jurisdictions hold that the company is not responsible for payment; but there is a growing minority of opinion which declares that, if the suicide was undertaken because of an "insane compulsion" without realizing the consequences of the act, the company is liable. As to the problem of workmen's compensation, Guttmacher and Weihofen[8] explain that, if a person's suicide is connected with a mental disorder arising from an accident at work, and the act is carried out without conscious volition to produce death, the case is compensable. However, if the person had the ability to recognize the purpose and the physical effect of the act, then the chain of causation is broken.

The Social Problem of Suicide

Vail[9] has raised the following questions regarding suicide: "To what extent is it given to man to take his own life?" and "What right do we have to interfere with his plans, if this is what he has decided to do?" Western civilization is sufficiently mature to face these challenging queries. An enlightened public can be led by physicians and sociologists, if the latter view suicide in the perspective of careful inquiry now applied to other diseases.

CARDIOVASCULAR RESPONSES TO TRANSCRANIAL ELECTRIC STIMULATION IN MAN AND DOG

D. Jeanne Richardson, M.D., Lawrence H. Gahagan, M.D., William H. Lewis Jr., M.D.,
Daniel Sheehan, M.D., New York, Edwin J. DeBeer, Ph.D., Kenneth I. Colville, Ph.D.
and
Charles H. Ellis, Ph.D., Tuckahoe, N. Y.

Factors that might contribute to the mortality associated with electroconvulsive therapy were sought in a study of 400 treatments. Most of the patients received thiopental (average dose 400 mg.) intravenously before the treatment, and all received succinylcholine chloride and artificial ventilation with oxygen during the period of apnea. Vagal arrhythmias (marked tachycardia, occasional cardiac arrest) never occurred in patients who had received atropine but occurred frequently in patients who had not. Extravagal arrhythmias also occurred frequently and were not uniformly preventable by either chlorpromazine or quinidine therapy. All patients had transitory increases of systolic blood pressure. The increases were about half as great in patients who had received tetraethylammonium chloride as in patients who were not so protected. Experiments involving bilateral adrenalectomy and transection of the spinal cord in dogs corroborated the impression that both vagal and extravagal mechanisms are activated by electroconvulsive treatment and can be depressed by appropriate medication.

Transcranial electric stimulation, when administered in electroconvulsive therapy, is a neurogenic stressor profoundly affecting the cardiovascular system. The most prominent circulatory responses so induced are disturbances in the initiation and conduction of the cardiac impulse and paroxysmal changes in the arterial pressure.

The understanding of these mechanisms is a matter of practical as well as theoretical interest, in view of the fact that acute circulatory disturbance is the most frequent cause of death in electroconvulsive therapy, whether it is given alone or in conjunction with such drugs as barbiturates and muscle relaxants. The death rate during and immediately after electroconvulsive therapy has been shown to be about 1 in every 1,065 patients treated [1]; in a study of 254 such deaths Impastato [2] found 40% to be of cardiovascular origin. He further showed that 27% of these fatalities were in 50-to-60-year-old patients. In the report of Maclay [3] on 62 deaths, 56% were in persons over 55 years of age.

These cardiovascular responses appear to be identical in man and in the dog. Therefore, animal in addition to human studies have been used in attempting to elucidate the underlying mechanisms.

Studies in Man

Electroconvulsive therapy (ECT) was administered in over 400 treatments. The ECT was modified by the intravenous use of barbiturates (thiopental or thiamylal sodium in most instances); succinylcholine (Anectine) chloride and artificial ventilation with 100% oxygen were given continuously during the period of apnea. Continuous electrocardiographic observations and frequent sphygmomanometric pressure determinations were made during each treatment.

Arrhythmias of varying degrees of severity occurred in the course of about 33% of the treatments. These arrhythmias were classified as vagal and extravagal. The vagal arrhythmias were characterized by marked slowing and occasional standstill of the heart. These were uniformly preventable by adequate atropinization. The extravagal arrhythmias consisted of frequent ventricular contractions, bigeminy and trigeminy, and, on a few occasions, runs of ventricular tachycardia. Various drugs, such as chlorpromazine and quinidine, were used to prevent the extravagal arrhythmias, but none of them was uniformly effective.

The treatment-induced pressor responses, manifested by a rise mainly in the systolic blood pressure, occurred in varying degrees in every patient. These were reduced to about one-half their usual magnitude by the prophylactic use of tetraethyl ammonium chloride. The use of phentolamine (Regitine) hydrochloride in patients with severe hypertension has been postulated, but such a patient has not yet been encountered by us.

Studies in Dogs

Transcranial electric stimulation was applied to dogs under comparable conditions, including continuous electrocardiography. Blood pressure, however, was recorded directly from a cannulated carotid artery with a Statham transducer and a Sanborn Polyviso.[4]

Read in the Symposium on Common Problems before the Joint Meeting of the Section on Anesthesiology and the Section on Nervous and Mental Diseases at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 11, 1959.

Direct recording revealed a transient fall in blood pressure occurring immediately after electrostimulation. This fall, presumably too brief to be detected in the human measurements, was abolished by atropine or tetraethylammonium chloride (TEA). Atropine sulfate, in doses as small as 0.036 mg. per kilogram of body weight, completely prevented bradycardia and vasodepression after transcranial stimulation. Bilateral vagotomy was performed on several of the dogs and was found to be fully as effective as atropine in abolishing the bradycardia and hypotension.

TEA exerted a partial protection against the blood pressure rise, similar to that seen in humans; that is, there was a rise but it was not so great as that seen during the control stimulation. Larger doses of a more potent ganglionic blocking agent—hexamethonium chloride in doses of 10 mg. per kilogram of body weight—eliminated both the hypotensive and the hypertensive responses of the arterial pressure.

The use of such adrenergic blocking agents as phentolamine and phenoxybenzamine hydrochloride (Dibenzyline) partially blocked the pressor responses to transcranial stimulation. Weil-Malherbe and others [5] had suggested that the pressor response was due to an increase in circulating epinephrine and arterenol. Therefore, bilateral adrenalectomy was performed and this reduced the blood pressure rise to one-third of that obtained before adrenalectomy was performed. The residual hypertensive effect remaining after adrenalectomy would appear to be due to neurogenic mechanisms, i. e., caused by the release of neurohormones from sympathetic nerve endings directly at receptor sites in the heart and blood vessels.

In addition to blocking the sympathetic ganglions and preventing the liberation of sympathetic materials from the adrenal medulla, interruption of the sympathetic system in its course from the central nervous system to the periphery was performed by transecting the spinal cord above the level of sympathetic outflow. Cutting the spinal cord at C-6 abolished the hypertensive response without essentially affecting the initial blood pressure fall. If vagotomy was then performed on the dogs with transected cords, no change occurred in the arterial pressure.

Extravagal arrhythmias were encountered in 4 of 15 dogs and ranged in severity from an occasional premature ventricular contraction to brief periods of coupled premature beats and even short bouts of ventricular tachycardia. In three of the four animals exhibiting extravagal arrhythmias the severity and duration of the arrhythmia progressively decreased over the course of the first three stimulations (administered at 15-minute intervals) and were completely absent thereafter. A similar decrement in the hypertensive response on repeated stimulation was not observed.

Comment

The relatively high incidence of arrhythmias in our series of patients may be partly explained by the facts that the majority were over 40 years of age and that many of them had preexisting cardiac disease (one had Stokes-Adams syndrome; another had an aneurysm of the abdominal aorta). Many of these patients had been refused treatment elsewhere.

Our results are somewhat at variance with those of Egbert and co-workers,[6] who found that increasing the dose of thiopental from 100 to 500 mg. reduced the incidence of circulatory reactions stimulated by electroshock therapy. The average dose given to our patients was 400 mg., and still there was a high incidence of arrhythmia and a significant elevation of blood pressure in more than 60% of our patients.

The cardiovascular response to transcranial stimulation appears to be the result of a generalized peripheral discharge of both branches of the autonomic nervous system. The cholinergic effects, bradycardia, and hypotension predominate during the first phase of the response; then the second phase, characterized by hypertension and extravagal arrhythmias, demonstrates the excessive sympathetic activity. The effect of vagotomy and cord transection would appear to show that the origin of the response is in the brain centers, which, on activation by the electric stimulus, initiate trains of impulses which are conducted peripherally through the parasympathetic and the sympathetic nervous systems.

The lessening in severity of extravagal arrhythmias on repeated stimulation in three of the four animals in which this type of activity was noted deserves further investigation. Such a phenomenon is suggestive of the depletion of some substance necessary to the reaction. Whether this substance is epinephrine or epinephrine-like, it is not possible to say at this time. The fact that the pressor response to transcranial stimulation did not decline with repeated stimulation would imply that circulating epinephrine is not greatly depleted.

Summary

In both man and dog there are cardiovascular responses of varying degree to transcranial stimulation. These responses consist of two phases. The first is predominantly cholinergic, characterized by bradycardia and hypotension, which may be prevented by the administration of atropine or by vagotomy. The second phase, characterized by hypertension and extravagal arrhythmias, is predominantly adrenergic and may be ameliorated by the use of ganglionic and adrenergic blocking

agents, bilateral adrenalectomy, and transection of the spinal cord above the level of sympathetic outflow.

USE OF ARTIFICIAL KIDNEY IN THE VERY YOUNG, THE VERY OLD, AND THE VERY SICK

William A. Kelemen, M.D.
and
Willem J. Kolff, M.D., Cleveland

Methods of protecting against alleged dangers associated with use of the twin-coil artificial kidney are described, and it is emphasized that reluctance of clinicians to use this therapy, which often may be lifesaving, is not justified. The wide range of usefulness is illustrated by case reports on application of artificial dialysis in a 16-month-old girl, a 77-year-old woman, and a seriously ill middle-aged man. In tangled diagnostic situations, dialysis should be done in the hope that the underlying problems may prove correctible.

Neither the age of a patient nor the severity of his disease need stand in the way of dialysis for the treatment of uremia if there is a chance for recovery or hope for prolongation of an enjoyable span of life. In the very young, when it is impossible to differentiate between poisoning, glomerulonephritis, endarteritis, or other conditions causing renal failure, treatment with the artificial kidney will gain time so that a definitive diagnosis can be made. In the very old, confusion, coma, depression, or dementia may not mean the unavoidable end but may prove to be a reversible state. This is likely if the patient was well just a few days prior to his illness. Cerebral symptoms need not contraindicate treatment with the artificial kidney if an increase in retention products, an imbalance of electrolytes, or the amount of edema indicates it.

A patient with severe infection, poisoning, or trauma may have oliguria and uremia and be comatose. It may be impossible to determine readily whether the coma is due to infection, poisoning, trauma, or uremia, but it will be possible to evaluate the uremia factor by eliminating it with dialysis. These seriously ill patients tend to have convulsions when they are very young and pulmonary edema and bronchopneumonia when they are very old. In both instances, ultrafiltration during dialysis may remove enough fluid to reduce the overhydration on which these complications are based.

Report of Cases

Case 1.—A 16-month-old girl was admitted to the Cleveland Clinic Hospital on the second day of complete anuria. She had been well until 12 days prior to admission, when she had coryza followed by profuse diarrhea for three days. She had no appetite and had vomited once. Her temperature was 102 F (38.9 C), and appendicitis was suspected. Ten milliliters of normal-colored urine was obtained over a 30-hour period.

On admission the child was restless, irritable, and crying. She was pale and her eyelids were slightly puffy. The blood urea level was 204 mg.

From the Department of Artificial Organs, the Cleveland Clinic Foundation and the Frank E. Bunts Educational Institute. Dr. Kelemen is now at 1361 E. Morehead Ave., Charlotte, N. C.

per 100 ml.; blood pressure was 118/70 mm. Hg, and pulse rate was 156. Otherwise there was little abnormality, and the fundi were normal. Findings on a roentgenogram of the chest and retrograde pyelograms were normal.

The child was treated conservatively, remained completely anuric, and deteriorated clinically. The first dialysis was performed six days after the onset of anuria, when the blood urea level had increased to 374 mg., serum creatinine to 10.3 mg., and uric acid to 13.3 mg. per 100 ml. (fig. 1). The left greater saphenous vein was used as the inflow tract to the artificial kidney. The dialysis and ultrafiltration lasted three hours and 45 minutes; the child's weight was reduced by one pound. A transfusion of packed cells was given during the dialysis to correct the severe anemia (hemoglobin level, 3 Gm. per 100 ml.). Clinical improvement occurred. The catheter remained in the left saphenous vein for administration of 40% invert sugar. The child began to void small amounts of urine with a specific gravity of 1.021, a trace of albumin, many leukocytes, a few erythrocytes, and 4 or 5 granular casts.

Since the volume of urine did not increase sufficiently and vomiting began to recur, a second dialysis was done on the 12th day after the onset of anuria. A catheter was placed in the right saphenous vein, and dialysis was done by way of both saphenous veins for four and one-half hours. The blood urea level was reduced from 184 to 33 mg. and serum creatinine from 8.4 to 2.5 mg. per 100 ml. Ultrafiltration reduced the child's weight from 13,500 to 10,900 Gm. (29¾ to 24 lb.). After the second dialysis, when the patient began to take oral feedings, the catheters were removed. Daily urinary output increased gradually to 640 ml.; on the 30th day after the onset of anuria, the blood urea level had decreased to 33 mg. per 100 ml. The child was discharged on the 33rd day, and at examination one month later she was well and seemed to have recovered completely.

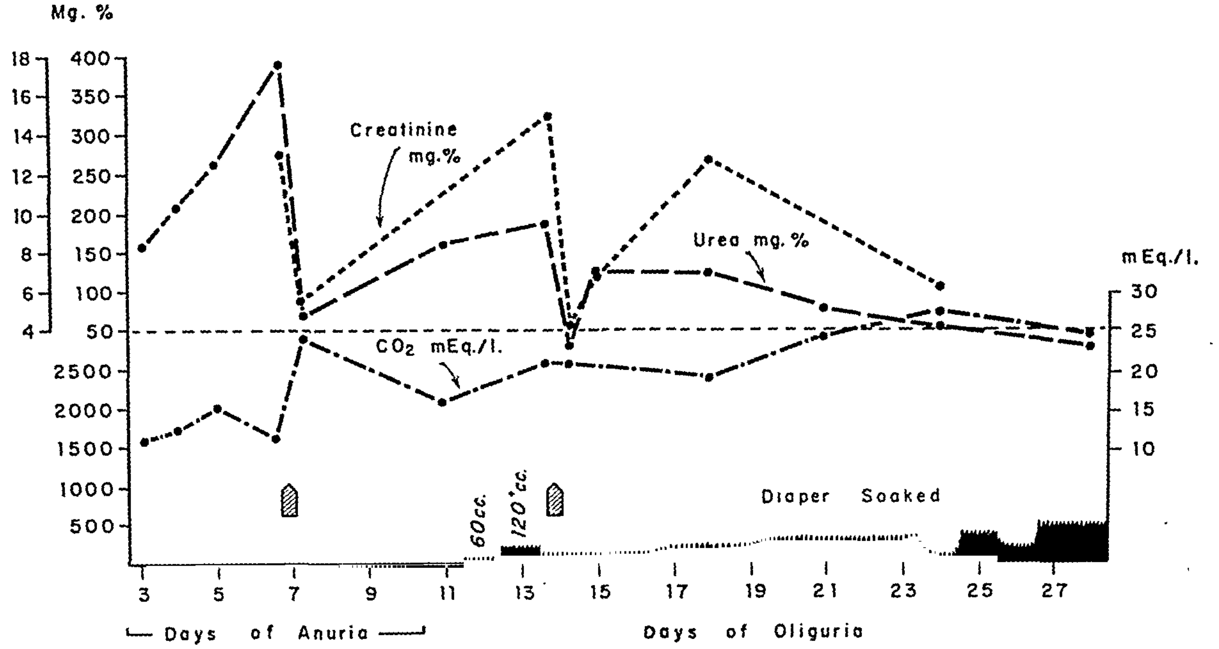

Fig. 1 (case 1).—Course in small child with renal failure of unknown cause and anuria for 11 days. Ultrafiltration was employed during both dialyses.

Case 2.—A 77-year-old woman was treated for lupus erythematosus for four and one-half years. Her disease was well controlled and she was in apparent good health until one week prior to admission, when she became anuric for two days, after which the volume of urine slowly increased. Three days prior to admission, chills, nausea, abdominal pain, and diarrhea developed.

On admission the patient was seriously ill; she was restless, confused, and nauseated and she vomited. She had abdominal pain that was not localized. A vesicular pustular eruption was spread over the face, trunk, and buttocks. The blood urea level was 195 mg.; serum sodium, 152 mg.; potassium, 6.4 mg.; serum chloride, 134 mg.; and hemoglobin, 14.8 Gm. per 100 ml. Carbon dioxide content was 8.6 mEq. per liter; cell volume, 44%; and leukocyte count, 6,700 per cubic millimeter, with normal differential. Although the hypernatremia and the hemoglobin content indicated dehydration, edema was present. The range of daily urinary output was 400 to 900 ml. Urinalysis revealed a specific gravity of 1.010, a trace of albumin, many erythrocytes, and 2 or 3 leukocytes. A roentgenogram of the chest showed evidence of left ventricular enlargement.

Attempts to improve the patient's condition with conservative treatment failed. The blood urea level increased to 300 mg., creatinine to 4.6 mg., and uric acid to 8.3 mg. per 100 ml.

On the 4th hospital day, the 10th day after the onset of oliguria, the patient's clinical condition became critical. Levarterenol (Levophed) and dextran were given intravenously in order to sustain the blood pressure until the artificial kidney was prepared. Dialysis was performed, and the clinical improvement was immediate and dramatic (fig. 2). On the 12th day the daily volume of urine increased to 1,500 ml. With steroid and antibiotic therapy the skin lesions faded and the patient became cheerful and happy, with a good appetite and a sense of well-being. She went home on the 18th day after the onset of oliguria; at the time of writing, six months later, she is reported to be doing well.

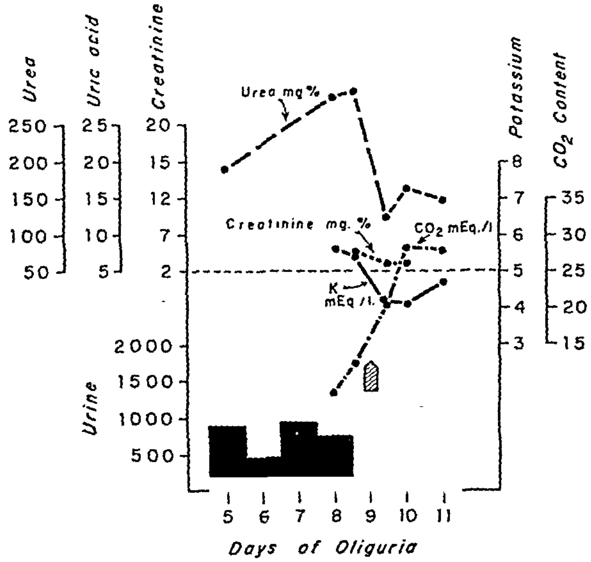

Fig. 2 (case 2).—Course in patient with lupus erythematosus with exacerbation and renal failure, showing results of dialysis.

CASE 3.—A 42-year-old man had a history of endocarditis with mitral stenosis and insufficiency, and some aortic insufficiency, but he had no previously known renal disease. Four weeks prior to his admission, influenza developed, with chills, fever, and neuralgia, which lasted 3 days and then recurred 10 days prior to admission. At that time, he had congestive heart failure and he was placed in an oxygen tent. He was treated with digitalis, cortisone, mercurial diuretics, and antibiotics without apparent success. Urinary output decreased to 300 ml. per day.

On admission to the Cleveland Clinic Hospital the patient was acutely ill, in congestive heart failure with pulmonary edema, in uremia, and semicomatose. Loud expiratory rhonchi and rales obscured the heart tones. We believed that he would not react to further administration of diuretics because the blood urea level was 294 mg. per 100 ml.; since he was in danger from heart failure and pulmonary edema, he was treated immediately with dialysis and ultrafiltration (fig. 3).

The serum potassium level, later reported to be 7.3 mEq. per liter, was in itself sufficient reason for immediate dialysis. Through ultrafiltration, his weight was reduced from 168 to 160 lb. (76.2 to 72.6 kg.). Within one and one-half hours, the signs of pulmonary edema had disappeared. Vigorous treatment with antibiotics and digitalis was started immediately. Three days later a second dialysis became necessary when the blood urea level had increased to 344 mg. per 100 ml. and clinical deterioration occurred, despite a urinary output of 1,850 ml. the previous day. Ultrafiltration was also employed during the second dialysis, and the weight was further decreased from 153 to 146 lb. (69.4 to 66.2 kg.). After this the patient gradually improved. He had a short acute depressive reaction from which he quickly recovered. He remembered nothing of any event during the previous three weeks. He left the hospital in good condition, and it was expected that he would soon be able to resume his occupation.

This man may have had subacute bacterial endocarditis superimposed on his preexisting rheumatic heart disease. Blood cultures remained sterile. The nature of the renal failure is not clear. Red blood cells and even microscopic hematuria were present, but otherwise the sediment showed little change. It is possible that emboli from the subacute bacterial endocarditis complicated whatever renal disturbance was present on the basis of heart failure. During the first week of his disease he was stuporous, disoriented, and sometimes restless, but there were no localizing symptoms. The cerebral dysfunction may have been due to a combination of prolonged anoxia caused by pulmonary edema and the uremia. It is unlikely that this man would have survived with conventional therapy alone. The turning point in his disease was brought about by the combination of ultrafiltration and dialysis.

Comment

Fear of alleged dangers of dialysis still prevents many clinicians from using the artificial kidney when it is indicated, especially when patients are very young or very old. We believe that the unfamiliarity with the present technique of using the artificial kidney is responsible for this unjustified fear. We will therefore consider what might be the alleged dangers or contraindications for the use of the artificial kidney in the very young, the very old, and the very sick. We will limit our consideration to the twin-coil kidney, which is now most widely used in the United States.[1]

Changes in blood volume of the artificial kidney could cause either shock or hypervolemia. This danger must and can be avoided. In small children, only one coil of the disposable twin-coil artificial kidney is used.[2] The priming blood is recirculated through the coil at an outflow pressure of 70 mm.

Hg. When the circulation of the child is switched in, without change in this outflow pressure, it may be assumed that there is no change in the blood volume of the artificial kidney and, therefore, that no change in the blood volume of the patient occurs. That this is true can be easily confirmed if the child is placed on a sensitive scale during the dialysis.

When the radial artery is small, as in the very young, or when there is hypotension, as in the very sick, it is best not to rely on the artery but, rather, to draw blood from a cannula in the saphenous vein which extends into the inferior vena cava. This cannula is brought out through a stab wound while the primary wound is closed. With due precaution the cannula may be used during the following days to administer a high-calorie (40% invert sugar or dextrose) solution to the patient; 10 mg. of heparin is added to each 500 ml. of fluid. The wound is covered with bacitracin ointment and a bandage. A safety curl on the leg is made so that the cannula cannot be pulled out.

The possibility of ultrafiltration has greatly expanded the usefulness of the artificial kidney. The problem of water balance is most important. Water of oxidation in itself may cause overhydration if there is a significant breakdown of the body tissues or if a high-calorie regimen is administered; thus, overhydration can occur even if the patient is given a minimal amount of water. Overhydration promotes the occurrence of hypertension, convulsions, and pulmonary edema. Therefore, ultrafiltration is combined with dialysis whenever a patient is overhydrated. Six hundred milliliters of ultrafiltrate may be removed per hour by adjusting a screw clamp on the outflow track which increases the back pressure in the artificial kidney.[3] Whereas decrease in pulmonary edema is obvious during dialysis, general clinical improvement should be evident on the following day. Sometimes it seems to be related to the removal of the excess fluid rather than to the removal of retention products.

In very old patients, sudden changes in blood pressure may easily provoke a stroke or coronary insufficiency. Changes in blood pressure during use of the twin-coil kidney nearly always can be avoided. If a rise in blood pressure occurs, temporary removal of a certain amount of blood from the patient's circulation is easily done, or one of the blood pressure–reducing drugs (e. g., pentolinium [Ansolysen], promazine [Sparine], or trimethaphan [Arfonad]) may be injected into the outflow line of the artificial kidney in small doses until the blood pressure is lowered. If a decrease in blood pressure occurs, a small (200 ml.) transfusion usually suffices to correct the blood pressure.

An electrocardiogram is constantly monitored on a Viso-Scope, and if, in the very sick, changes occur that are considered undesirable, the dialysis is temporarily discontinued. It is well to realize that the first hour of dialysis is by far the most important in terms of removal of retention products and correc-

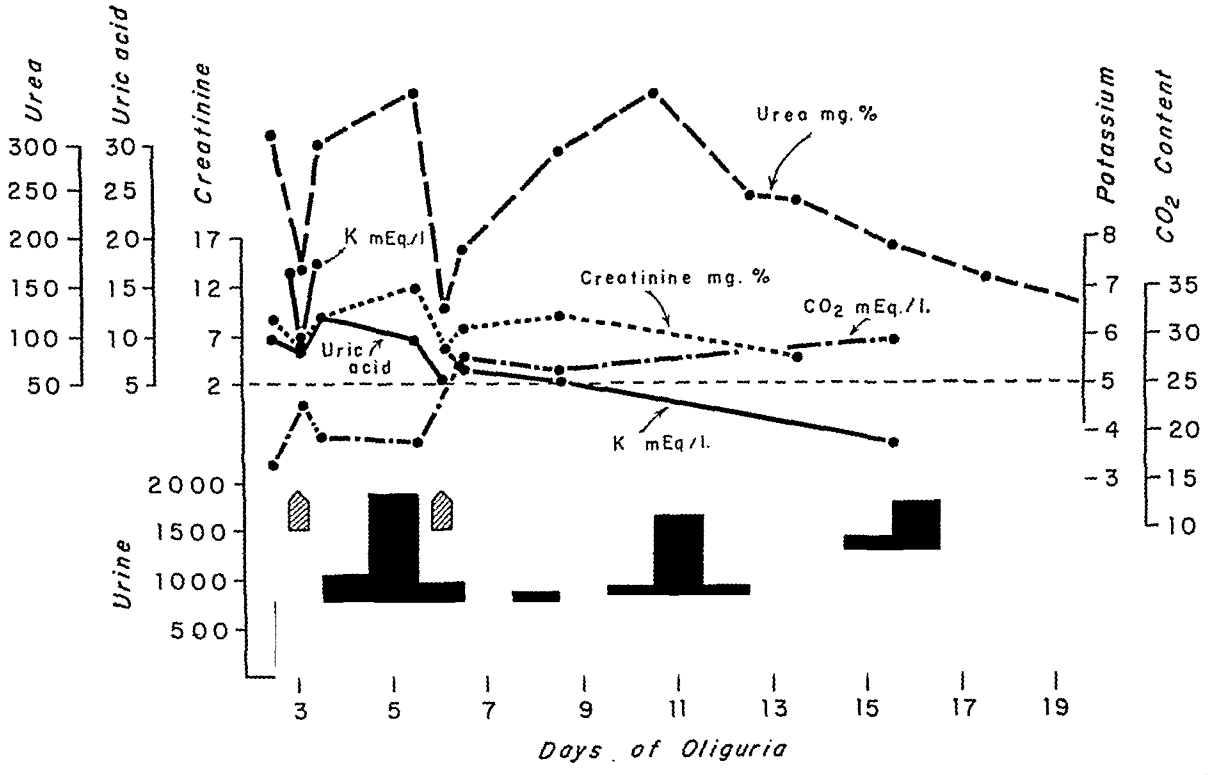

Fig. 3 (case 3).—Course in patient with congestive heart failure and pulmonary edema due to rheumatic heart disease. Development of primary renal failure made usual congestive failure therapy unsatisfactory. Ultrafiltration for removal of edema fluid was employed during both dialyses.

tion of electrolyte imbalance and that thereafter the effectiveness of dialysis decreases in proportion to the length of its duration. After three hours of effective dialysis, even what had been a dangerous degree of uremia will be sufficiently reduced to allow a pause of one or two days before another dialysis. Both arterial and venous cannulas may be left in the blood vessels; they are kept open by injections of 2 mg. of heparin in 2 ml. of saline solution every two hours in each cannula.

Large abrupt changes in electrolyte values, especially in the very old, may be expected to be followed by undesirable side-effects. Electrolyte changes should be made gently. For example, if the patient's serum sodium level is extremely low, we adjust the sodium concentration in the rinsing fluid of the artificial kidney to a level midway between that of the patient's serum and normal. A high potassium level is not drastically reduced all at once, otherwise arrhythmias or digitalis intoxication may appear.[4] A sudden dehydration may be followed by mental changes resembling catatonic psychosis.

The danger of hemorrhage is slight since we have learned to use regional heparinization. In our hospital about one-third of all dialyses are performed with regional heparinization. With this technique a constant infusion of heparin is administered into the inflow line of the artificial kidney and, at the same time, the appropriate amount of protamine sulfate is constantly administered into the inflow line to the patient.[5] This assures a prolonged clotting time of the blood in the machine and a normal clotting time of the blood in the patient.

For unknown reasons it is impossible to improve a low blood pressure by the usual means in some patients seriously ill with uremia, but after dialysis the blood pressure often becomes stabilized. Our 77-year-old patient (case 2) required continuous infusion of dextran and arterenol to maintain the blood pressure prior to connection to the artificial kidney. After the dialysis the administration of these drugs could be stopped.

Large amounts of blood or packed cells cannot be transferred in anuric patients. The risk of overloading the circulation and of causing pulmonary edema is too great. In the child (case 1), who had a hemoglobin content of only 3 Gm. per 100 ml. at the onset of dialysis, 400 ml. of blood could be transfused during the period of ultrafiltration. This safely improved the child's hemoglobin content, but without ultrafiltration such a transfusion might have led to convulsions. In the woman (case 2), 1,600 cc. of blood was administered during treatment with the artificial kidney. Thus, anemia can be adequately improved when ultrafiltration is employed to reduce the circulating blood volume. Exsanguino transfusion (replacement)[6] can be done after dialysis by utilizing the two cannulas already present. For each volume of blood or cells transfused, an equal volume is withdrawn. Sometimes, this is followed by a reduction of hypertension.

Early and frequent dialysis in patients with acute uremia can maintain clinical well-being, as was convincingly shown by O'Brien and associates,[7] who performed daily so-called prophylactic dialysis. We do not dialyze daily because this is not necessary with an effective dialyzer; we agree, however, that frequent dialyses, every two or three days, will maintain the patient's well-being.

Conclusions

In conclusion, we believe that the artificial kidney may be safely used in the very young, in the very old, and in other patients no matter how gravely ill, when it is skillfully handled. The advantages and the virtual certainty of clinical improvement whenever uremia or overhydration play a part in the clinical picture far outweigh the alleged dangers of dialysis. When the recoverability of a patient is questionable, he should be given the benefit of the doubt. Often, patients are admitted in dire states, the multiple problems together with uremia appear to be overwhelming, and some clinicians doubt the wisdom of pursuing intensive therapy. The "wait-and-see-er" loses precious time; delay lessens the effectiveness of ultimate dialysis. Finally, in tangled diagnostic situations, dialysis should be done in the hope that the underlying problems may prove to be correctible.

2050 E. 93rd St. (6) (Dr. Kolff).

The patients reported on were treated in collaboration with the following physicians from the Cleveland Clinic: case 1, Dr. Robert D. Mercer, department of pediatrics; case 2, Dr. John R. Hascrick, department of dermatology; and case 3, Drs. Leonard L. Lovshin and Ray A. Van Ommen, department of internal medicine.

The twin-coil kidney was manufactured and presented by Travenol, Baxter Laboratories, Morton Grove, Ill.

EXPERIENCE WITH HALOTHANE (FLUOTHANE) IN MORE THAN FIVE THOUSAND CASES

John Abajian Jr., M.D., Edward H. Brazell, M.D., Gino A. Dente, M.D.
and
Ernest L. Mills, M.D., Burlington, Vt.

As a result of this extensive experience with a series of entirely unselected cases, it is concluded that halothane is a safe and predictable anesthetic when it is administered with equipment which permits accurate control of the vapor concentration and when concentrations are never allowed to exceed 2%. Special equipment and techniques believed necessary will be described in a subsequent paper. With such control, severe hypotension has ceased to be a problem, and there has been no evidence of hepatic, renal, or undue myocardial toxicity. Addition of a muscle relaxant was rarely necessary. There was remarkable absence of salivary and bronchial secretions. Further studies are being conducted to clarify the supposed dangers of using halothane in closed circuit.

Halothane (Fluothane) is a relatively new, potent, nonflammable, nonexplosive, volatile anesthetic agent which was introduced by Raventos[1] in May, 1956. It was made available to the American market in April, 1958. Its formula is 2-bromo-2-chloro-1,1,1-trifluoroethane, with the structural formula shown in figure 1.

Clinical Material and Methods

Halothane has been employed in more than 5,000 cases since November, 1956. During the first six months, 18% of the total anesthetizations done on our service were with halothane and oxygen. Since that time halothane has been used in over 40% of all anesthetizations. It has been employed by the attending staff and by the resident staff in the teaching hospitals of the University of Vermont, College of Medicine. A breakdown by type of case is given in the table.

In the first 100 cases conventional methods of administering volatile anesthetics were used, including "closed," "semiclosed," and "open" systems. The actual concentrations of halothane were, of course, unknown. In all subsequent cases not only were the concentrations of the agent accurately known but they were 2% or under. Except as noted, it is these cases, in which controlled concentrations were used, that are reported in this paper.

In adults an ordinary face mask was used on the conscious sedated patient, beginning with a 2% vapor concentration. With children, a "space helmet" was employed, or occasionally the delivery tube from the gas machine was held 2 or 3 in. away from the nose while the anesthetist talked to the child. When this technique was employed, 3% of the agent was delivered from the tube because of the dilution by admixture with air. When unconsciousness occurred, this technique was quickly changed to one employing a mask and bag, utilizing nonrebreathing valves.

Originally, the typical premedication employed for a young healthy adult was 75 mg. of meperidine with 0.4 mg. of scopolamine hydrobromide administered one and one-half hours preoperatively and 50-100 mg. of pentobarbital sodium given one hour preoperatively. During the last year this has been changed to a mixture of 40 mg. of alphaprodine (Nisentil) hydrochloride, 0.4 mg. of scopolamine hydrobromide, and 0.8 mg. of levallorphan (Lorfan) tartrate. Pediatric premedication has been with 24 mg. of alphaprodine hydrochloride, 2.5 mg. of levallorphan tartrate, and 0.15 mg. of scopolamine hydrobromide per 50 lb. (23 kg.) of body weight, administered intramuscularly 45 minutes preoperatively.

Atropine sulfate was not administered intravenously routinely before or during induction. It was given only in the presence of moderate bradycardia. The halothane was administered with oxygen alone, and intravenously given ultra-short-acting barbiturates or nitrous oxide were not employed in this series.

Results

Results were not good when halothane was administered in an inadequately controlled manner, as evidenced by the reported cardiac arrests, by moderate to severe hypotensive episodes, by arrhythmias, and by occasional respiratory acidosis from hypoventilation. When employed in the current, accurately controlled manner, the results have been very gratifying to both the anesthesia and the surgical staffs.

Mortality and Morbidity.—The following observations apply only to the cases in which this controlled manner was used and exclude the first 100 cases.

In the two-year period covered by the remainder of this series there were 23 deaths associated with surgery (occurring within 48 hours postoperatively). Seven of these patients had received halothane; of these seven, six had a physical status of grade 5 or

---

From University of Vermont, College of Medicine.

7 (American Society of Anesthesiologists classification). All left the operating room in at least as good condition as when they entered. These patients died at periods ranging from 8 to 36 hours postoperatively, and there was agreement among the surgeons and the anesthetists that anesthesia played no part in the deaths. The remaining patient died in the operating room. This was a patient with a ruptured abdominal aortic aneurysm operated on with use of hypothermia. Asystole developed when the anastomosis was opened after four and one-half hours of aortic occlusion. The resuscitative attempts were unsuccessful. It was not felt that halothane had contributed to this death.

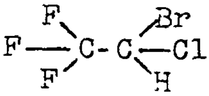

Fig. 1.—Structure of halothane (Fluothane).

No evidence of hepatotoxic or nephrotoxic effects was noted in this series, which, indeed, included patients with preoperative hepatic and kidney disease. Since adequate studies showing lack of toxic effects of halothane on the liver had been made by others, it was not felt necessary to repeat these.

Induction of Anesthesia.—Induction of anesthesia was extremely smooth. Patients accepted 2% halothane readily. There was a complete absence of nausea or vomiting on induction, minimal coughing or breath-holding, and complete absence of cyanosis. Only about 3% of the patients exhibited any appreciable excitation symptoms. The surgical anesthetic stage was attained in 10 to 15 minutes with 2% halothane, when used in the manner described above.

Maintenance.—A 2% concentration of halothane was adequate for the maintenance of abdominal relaxation in 80% of abdominal operations without the addition of a muscle relaxant. In neurosurgical cases, and in other cases where there were minimal painful stimuli, the average maintenance concentration for light surgical anesthesia after equilibration was 0.4 to 0.6%. For operations not requiring muscular relaxation, it was found that a concentration of from 0.4 to 1.25% was usually sufficient.

Emergence.—Emergence from anesthesia was in the vast majority of cases extremely rapid. In those cases where anesthesia had been maintained with a concentration of 1% or less, return to consciousness invariably occurred within a period of five minutes. In those cases which necessitated halothane concentrations of 2% for maintenance, emergence was somewhat delayed. Only rarely, however, was a patient unable to respond to his name by the time of transfer from the stretcher to the bed (average time about 15 minutes).

Cardiovascular Effects.—Three hundred seventeen cases were analyzed for blood pressure data. Figure 2 shows the maximum drops in systolic and diastolic pressures observed during the first hour of anesthesia. The fall in these pressures usually occurred at about one hour after induction. It can be noted in figure 3 that in less than 15% of cases was the fall in blood pressure at the end of an hour more than 20 mm. Hg. Blood pressure "drops" observed were less than those in adequately managed cases in which spinal anesthesia was used.

In about 100 cases electrocardiograms were monitored. Results with halothane were comparable to those seen with other anesthetic techniques. The incidence of pulse abnormalities, other than a definite tendency to bradycardia, was found to be no greater than with any other commonly used anesthetic agent. The moderate bradycardia observed was frequently associated with a hypotensive trend, and both almost always promptly reversed with the administration of atropine intravenously. Although epinephrine was used in over 75 local anesthetic infiltrations during halothane anesthesia, the incidence of arrhythmias was no greater in this group. Special attention was paid to these cases, since it has been said that the use of epinephrine with halothane is contraindicated.[2]

Although general surgical oozing and bleeding were thought to be diminished, it seemed to the hospital staff that halothane increased postpartum hemorrhage. This occurred in conjunction with the deeper planes of anesthesia obtained with halothane, as compared to nitrous oxide, which had been used previously in the delivery rooms. However, when halothane was employed, with patients kept in the same light planes of anesthesia produced by nitrous oxide, this tendency to increased bleeding was not present. The skin was warm, pink, and dry. Superficial veins were usually distended.

Breakdown of Cases in Which Halothane Was Used, by Type of Procedure

Type of Surgery	No. of Cases
Eye	198
ENT and Oral	
Tonsils and adenoids	1,612
Other	498
Orthopedic	213
Thoracic	
Pulmonary and esophageal	142
Cardiac	22
Neurological	
Craniotomy	52
Other	75
Obstetric and Gynecologic	
Cesarean section	7
Other	862
Urologic	130
General	1,318
	5,129

Respiratory Effects.—Ventilatory depression with this agent was observed to be proportional to the concentration used, as is well known to be the case with most anesthetic agents. With a concentration of 2% or less, little or no hypoventilation was noted. Intercostal paralysis or paresis was rarely seen. All patients breathed spontaneously except those with open chests or those in whom relaxants were used.

Measurements of tidal volume and rate in over 400 cases were made and the findings compared to the Radford nomogram.[2A] Ninety per cent showed less than a 10% deviation from the predicted value. In practically all the remaining cases the intravenous administration of levallorphan promptly reversed the respiratory depression. Measurements of end-expired pCO_2 were in line with the above tidal measurements. Results of 10 arterial pH determinations performed at random were also all within normal limits. Apnea and breath-holding were rarely encountered.

A definite tendency to tachypnea was found with this agent. It was noted that this was considerably reduced by the use of narcotics, even when given with a narcotic antagonist. Occasionally such administration of narcotic plus antagonist was used during the course of an operation to alleviate existing tachypnea. This was usually successful.

The compliance factor [2B] was determined in a group of thoracic surgery cases by changing from halothane to thiopental–nitrous oxide. It was easier to inflate these patients' lungs manually when halothane was used. Also, when a mechanical ventilator was used, less pressure frequently was required to attain a particular tidal exchange with halothane than was the case with thiopental–nitrous oxide.

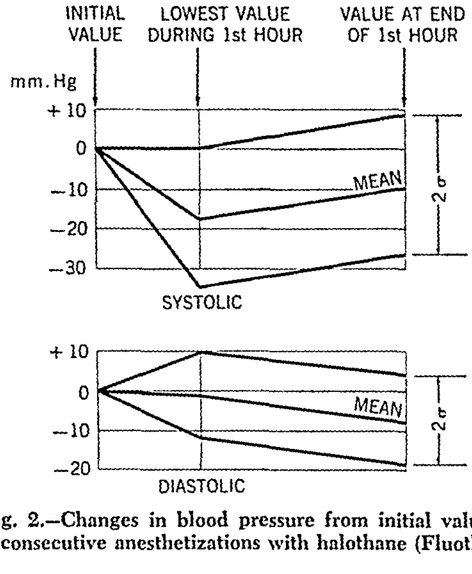

Fig. 2.—Changes in blood pressure from initial values in 317 consecutive anesthetizations with halothane (Fluothane).

Emphysematous and asthmatic patients seemed to be improved on inhalation of halothane, as manifested by decreasing rales and a shortening of the expiratory phase.

Reflexes.—With 2% halothane the laryngeal reflexes were sufficiently obtunded to allow easy intubation in more than 90% of the cases. With halothane anesthesia, use of muscle relaxants to facilitate intubation was necessary in only 5% of the patients. However, the time available for this maneuver was only about one-fourth that available when ether anesthesia was used. At times, when intubation was attempted on patients in unduly light levels of anesthesia, where movements of extremities were noted, the reaction to this intubation was extremely short and not intense, practically never resulting in cyanosis.

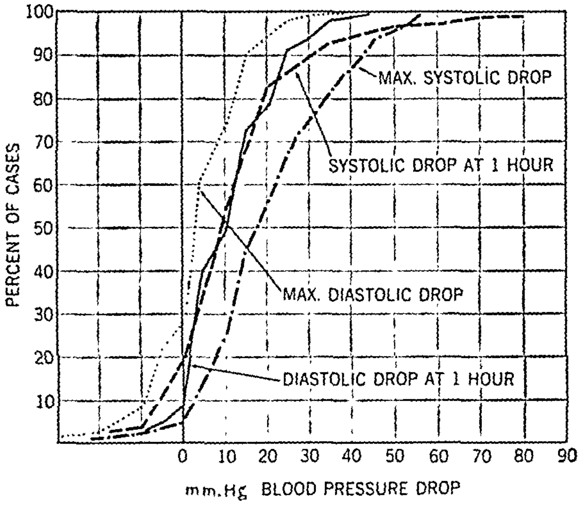

Fig. 3.—Percentage of patients whose blood pressure drop (from initial value) was less than value indicated along horizontal axis.

The oropharyngeal reflexes were obtunded in even lighter planes, occurring with the use of 1% halothane, so that oropharyngeal airways were easily inserted and tolerated. The ear, nose, and throat service frequently commented on the extreme quietude of the oropharyngeal reflexes when this agent was used. Oral surgery was usually satisfactory even when the level of anesthesia was such that patients could move their extremities.

Secretions.—The absence of salivary and bronchial secretions was remarkable. Patients were dry during induction, dry during maintenance, and dry on emergence, requiring far less tracheal suction than was customarily employed prior to the use of halothane. The few patients anesthetized without premedication were dry with respect to salivary and bronchial secretions. Our thoracic surgical service has commented on the fact that the need for postoperative "tracheal aspirations" has markedly diminished.

Nausea and Vomiting.—The incidence of postoperative nausea and vomiting in 500 cases selected at random was found to be about 2%. No vomiting was observed in 15 patients anesthetized with halothane after recent ingestion of food.

Relaxation.—In the 20% of patients undergoing abdominal surgery in whom muscle relaxants were required for adequate exposure, the amounts needed were about one-half of those usually employed with thiopental–nitrous oxide. Relaxants were not required in cases of open-chest surgery to obtain quiet operative conditions.

Methods of Achieving and Maintaining Desired Levels

It was found that the usual clinical signs for estimating levels of anesthesia were frequently deceptive. Many times patients appeared adequately anesthetized but responded with movement when surgery began. Time and the concentration of the agent employed seemed to be a more reliable indication of level of anesthesia. For instance, 10 to 15 minutes of a 2% halothane concentration almost consistently produced second-plane, third-stage anesthesia. Signs of third-plane, third-stage anesthesia were observed in less than 2% of the patients, and these were usually debilitated. To produce first-plane anesthesia, concentrations of about 0.75% could be fairly well depended on.

It may be observed from the above comments that halothane employed in this manner has an absolute bottom such as one encounters when using incomplete agents such as nitrous oxide or ethylene. This last statement cannot be sufficiently emphasized. The semiclosed system with low flows with only oxygen as a diluent was the predominant technique employed in this study (figs. 4 and 5).

Comment

In more than 5,000 administrations of halothane, the hypotensive episodes observed to date have not seemed to be a liability. In the cases observed in this series, we have seen no mortality or morbidity associated with the hypotensive effects of this agent.

Moreover, the hypotension observed during open-chest surgery seemed to be of somewhat greater magnitude with halothane than with other agents. But it should be noted that mortality and morbidity do not appear to result under these circumstances. In our series no attempts were made to exclude patients with preexisting hypotension such as that found in shock and hemorrhage.

In order to deliver known concentrations of this agent, it is necessary to have special equipment and employ special techniques. A subsequent paper will deal with this aspect of the subject.

With high flows, use of this agent is expensive. It is possible, however, to use it with low flow rates, so that the cost is comparable, for example, to that of cyclopropane. This also will be discussed in a subsequent paper.

Halothane, when used in high and uncontrolled concentrations, can produce complete cardiorespiratory arrest in a matter of minutes, as was evidenced in the three instances which occurred during induction in our first 100 cases. Again, we want to emphasize that there is a definite need for precise knowledge of the exact concentration administered at all times. The apparent wisdom of this approach was pointed out many years ago by Snow[3] and recently by Waters.[4] We place this safe value at 2%. However, it is possible that we may, in the future, revise this upward if experience permits.

At present the employment of open-drop or closed systems with halothane seems to be fraught with great danger to the patient. Closed systems, as ordinarily used, may produce high concentrations with disastrous results.

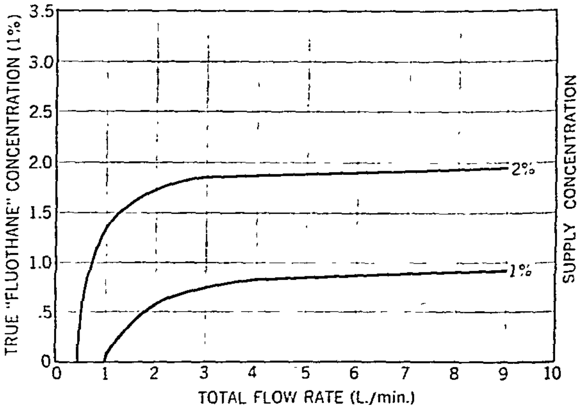

Fig. 5.—True halothane (Fluothane) concentration versus total flow in semiclosed system, with the patient absorbing 0.25 liter per minute of oxygen (metabolic) and 0.01 liter per minute of halothane (into fat depots) (time constant at about 100 hours).

However, recent data from Robson and co-workers[5] and Raventos and Duncan,[6] and corroborated by us with a few preliminary measurements made with an infrared spectrophotometer in an anesthetic system, seem to indicate a fairly constant uptake rate of about 10 cc. of halothane vapor per minute into the fat depots. This is not at all surprising when one considers the oil-water solubility ratio of this agent. The rate at which halothane is deposited in the body fat[5] seems to have a time constant of about 100 hours; that is, it takes about 100 hours for the concentration of halothane in the fat to attain ⅔ of its final value. If the above measurement can be definitely established, it is possible that in the future closed systems for maintenance can be safely employed.

In our present studies we are employing a 0-to-30-cc. oxygen flow meter. In order to deliver 10 cc. of halothane vapor from the kettle, one must flow about 20 cc. of oxygen through the kettle (depending on the ambient temperature). One now merely adds sufficient oxygen, in a bypass around the kettle, to make up the metabolic need for oxygen.

This technique, monitored with an infrared spectrophotometer, has been employed in 50 patients. The minimal changes in concentration seem to substantiate the validity of the above assumption. This would bring the cost of halothane to about 45 cents per hour. The undesirable results reported by Burnap and co-workers[7] are attributable to the use of closed systems in conventional ways. When halothane is employed in this manner, it is almost impossible to know the actual concentrations.

At present we use this agent whenever a general anesthetic agent is indicated, except when other agents are used for purposes of resident training. The use of a nonflammable and nonexplosive anesthetic agent with high oxygen concentrations, which permits utilization of cautery in the operating room, is a distinct advantage.

Hypotension associated with the use of this agent occurred in the operating room only, with practically no postanesthetic hypotension. This is in sharp contrast to the postanesthetic hypotension often associated with the use of cyclopropane.

There are many characteristics of this agent which resemble those of chloroform. However, there are two striking differences, namely, halothane is not hepatotoxic and emergence is more rapid.

Results of Other Workers.—Other workers have obtained results which differ from those obtained by us. Devine and co-workers[8] for example, have reported respiratory acidosis associated with hypoventilation when halothane is employed in reported concentrations of 1.5% or less. We feel this figure is incorrect and should be much greater.

The figure of 1.5% was derived from the assumption that the gas issuing from the kettle was 20% halothane. This does not agree with observations made by us. At 24 C, which is an average room temperature, we find the concentration of halothane issuing from the Morris copper kettle to be about 39%. This is consistent with the theoretical predicted value based on known vapor tension data and also with the fact that this model of copper kettle does, indeed, saturate the gas leaving it with halothane at the low 2-to-3-liter flow rates used. Thus, if the temperature had been 24 C, average room temperature, the figure of 1.5% should be revised to 2.93%.

To have obtained a 20% vapor from the kettle, the kettle temperature would have had to have been about 10 C. Such ambient temperatures in operating rooms are rarely encountered, even in Vermont.

The difference in our experience with respect to nausea and vomiting from that reported by Stephen an co-workers[9] (2% versus 4.7%) is due, we believe, to the fact that we employ only oxygen to vaporize halothane and not nitrous oxide, which, in itself, can account for considerable nausea and vomiting. The lesser degree of hypotension observed by us, we believe, can be attributed, in part, to the fact that preliminary administration of the ultrashort-acting barbiturates was not used by us.

Gain and Paletz[10] and Chang and co-workers[11] have reported large blood pressure drops. It may not be amiss to comment again that the above authors did not administer this agent with known controlled concentrations. Severinghaus and Cullen have succinctly summarized the influence of halothane on the myocardium with the statement, "It is likely that all volatile and gaseous anesthetics including Fluothane depress the myocardium equally when given in doses that depress the central nervous system equally. This implies a fundamental similarity in the mechanism of the depression of the two organs, perhaps related to lipid membrane behavior."

Summary and Conclusions

As a result of our experience with halothane (Fluothane) in more than 5,000 entirely unselected cases, we have come to regard it as a highly satisfactory anesthetic agent when administered with equipment which permits accurate control of the vapor concentrations.

It has been our experience that, when used in this fashion and when concentrations are never allowed to exceed 2%, halothane is a safe and predictable anesthetic. It permits smooth induction, early obtundation of pharyngeal and laryngeal reflexes, absence of salivary and bronchial secretions, adequate muscular relaxation for most surgical procedures, and an early return not only to consciousness but also to orientation as to person, time, and place.

In our hands, since accurately controlled administration has been employed, hypotension has ceased to be a problem and there has been no evidence of hepatic, renal, or myocardial toxicity. The use of halothane in closed circuit has been regarded as highly dangerous, and, although new evidence casts some doubt on the necessity for its proscription, further work will be necessary to clarify this picture.

THE MEDICAL PROGRAM OF THE VETERANS ADMINISTRATION

George E. Armstrong, M.D., New York

The veteran population of the United States, numbering more than 22 million in 1958, presents formidable medical problems. Approximately 1,250,000 veterans were 65 or more years old at that time. There were 172 Veterans Administration hospitals in operation. The medical program of the VA has paralleled the general advances in American medicine, and the VA has maintained a position of leadership in the work of rehabilitation. A program of education and training begun in 1946 has been extended to 72 medical schools. A program of medical research has grown to include more than 6,000 projects in VA laboratories. Although the veteran population is expected to decline, the demand for medical services, especially in the geriatric and neuropsychiatric fields, must be expected to continue or even to increase for many years.

In 1950 the medical program of the Veterans Administration was described in The Journal as a report from the Special Medical Advisory Group under the editorship of Dr. Roy E. Kracke.[1] This publication dealt in considerable detail with the history and legal background of the department of medicine and surgery and summarized the events which led to the reorganization of the VA medical program in 1945. The present paper proposes to supplement the report of 1950 and to present some of the more recent developments in the programs under which medical care is now being provided for American veterans.

In presenting this report as a spokesman for the Special Medical Advisory Group, I am pleased to call attention to the tremendous contribution which American medicine has made, and continues to make, to the total VA program. In this cooperative effort there has been an ever-increasing degree of understanding between practicing physicians and VA staffs' general acceptance of mutual obligations toward veteran patients and, finally, a feeling of national pride in our democratic system which provides excellent medical care for the men and women who have earned their eligibility through service to the country.

Medical Responsibilities

The basic medical responsibilities of the Veterans Administration can be described and predicted with considerable accuracy in terms of the present veteran population, the distribution of ages, known trends in the occurrence of disease and disability, and certain other established factors. As of June 30, 1958, the total veteran population of the country was 22,727,000. Although the total number of veterans is expected to decline, the demand for hospitalization and medical service will continue, or even increase, in certain categories for many years. This forecast is based in part on the medical requirement of veterans aged 65 or older. About 265,000 veterans attained the age of 65 in the fiscal year 1958. Of all veterans in civil life June 30, 1958, approximately 1,250,000 were 65 or more years old. In 1960, nearly 1,800,000 and in 1965, about 2,300,000 veterans will be aged 65 or over. These trends have served to focus attention of the Veterans Administration on the problems and challenges of providing geriatric care.

Attention is particularly directed to the medical requirements of the large group of elderly veterans hospitalized for neoplastic and cardiovascular disease, for chronic respiratory conditions, and for long-term neurological and psychiatric disorders. Surveys show that the older veteran patient is affected to a greater extent by these and other chronic disabilities or similar conditions requiring longer periods of treatment and convalescence than the younger patient. Veterans hospitalized for long-term illness (hospital stay in excess of one year) account for almost half of the total VA hospital capacity. This "freezing" of beds requires the Veterans Administration to exert especial vigilance regarding factors controlling length of stay and turnover among hospital patients.

Outpatient Medical Care

Veterans are provided with medical and dental care for service-connected disabilities by VA outpatient clinics and by private physicians and dentists furnishing services on a fee basis. Under these programs, medical care is provided with greater economy to the government and convenience to the veteran than the costly alternative of hospitalization. More than 2 million outpatients received medical services from VA outpatient staffs or fee basis physicians during the fiscal year 1958. Hometown (fee basis) medical care is used if (1) the demand for service exceeds the capacity of the clinic, (2) the patient requires a specific type of treatment not available in the clinic, or (3) travel to the clinic creates an undue hardship for the patient. During the last fiscal year, 36,300 physicians and 12,500 dentists participated in the fee basis program. Also participating in the hometown program were retail pharmacies which supplemented VA pharmacies by filling 628,000 prescriptions for veterans. The hometown medical program also provides community home nursing care, especially to patients convalescing from long-term illness.

To improve the quality of medical care the Veterans Administration has adopted the policy of combining, where feasible, activities of outpatient clinics and hospitals in the same locality. Although such arrangements have generally resulted in significant economies, financial advantage has not been a dominant consideration. A total of 19 such consolidations have been effected since 1950.

During recent years, important changes in medical practice have produced a steady increase in the work load and cost of outpatient services. The use of tranquilizer drugs has made possible and desirable the treatment of many persons on an outpatient basis who would have previously required hospitalization. Successful use of antibiotic drugs in the treatment of tuberculosis has likewise shortened the duration of hospitalization and increased the need for outpatient service. To a lesser extent, advances in the management of hypertension and cardiovascular disease have had a similar effect. Medical and research staffs of the Veterans Administration have participated actively in bringing about these and other developments. There can be no doubt as to the professional, social, and economic benefits ultimately to be derived from such trends. They do, however, necessitate a flexible administrative approach which is willing and able to meet the changing situation with appropriate shifts in organization and facilities.

The Hospital Program

At the end of fiscal year 1958, there were 172 VA hospitals in operation. Most of these hospitals provided care to patients of all types. On the basis of the medical type of the majority of patients under care, there were 20 tuberculosis hospitals, 40 neuropsychiatric hospitals, and 112 general medical and surgical hospitals.

In response to a request from Mr. Sumner G. Whittier, administrator of veterans affairs, the President has recently issued a new and important policy in reference to the VA hospital program. Under this new policy the total authorized capacity of the Veterans Administration hospitals is fixed at 125,000 beds. All future construction to provide beds or hospitals for replacement and modernization, or to compensate for major geographical shifts in veteran population, will be within this over-all total. It is further provided that beds or hospitals, within the fixed total, can be shifted from one use to another or from one geographical situation to another in response to advances in medical treatment.

This new policy represents an important milestone in the development of the VA medical program. It provides the necessary flexibility to convert beds from one diagnostic category to another or to make changes consistent with local requirements without threatening the system as a whole. Under this policy the hospital program will be more predictable in many aspects. The improvement in administrative stability is well calculated to maintain or improve the quality of professional care. Furthermore, the policy will help to clarify the obligation of the Veterans Administration to provide hospitalization to veterans with non-service-connected disabilities. Under the law, the Veterans Administration provides hospitalization to veterans with non-service-connected injuries or illness if it is determined that the veteran is unable to pay for such care and if a bed is available. In the past, a great deal of controversy has been due to the lack of clearly authorized limits for the total VA hospital system on which the availability of beds could be defined. Under the new policy the availability of beds can be determined as the difference between the number required by veterans with service-connected conditions and the total capacity of 125,000 beds. First priority always goes to the veteran who seeks hospitalization for a service-connected condition.

As already mentioned, the VA hospital program is profoundly influenced by the demand for long-term hospitalization. The length of stay in the hospital is directly related to the age of the patient population and to the incidence of chronic or irreversible disabilities. It is estimated that the median length of stay of all patients admitted to VA hospitals is about 21.5 days. It is difficult to make any valid comparisons between VA hospitals and private hospitals in this respect, because of the great difference in the type of patient being served. More than one-third of all VA patients are hospitalized for periods in excess of five years, and more than one-half of the large group of neuropsychiatric patients remains in the hospital for five years or longer.

During the fiscal year 1958, the average daily patient load in all VA hospitals was 111,599. Fifty-one per cent of these were classified as psychiatric patients. The remaining patients were distributed as follows: tuberculous, 10%; general medical and surgical, 35%; and neurological, 4%.

An annual sample census provides detailed information on the clinical and eligibility status of patients under VA care on a typical day. The most recent report (Nov. 30, 1957) on 113,000 patients hospitalized under VA auspices showed that about 400, or 0.4%, were nonveterans for whose care the Veterans Administration received reimbursement. Included in this group were military personnel on active duty, federal government employees who were injured or disabled in the course of their employment, and persons requiring emergency hospitalization who were admitted as a humanitarian measure. The remaining patients were veterans who may be classified in three eligibility groups as follows: 1. There were 34.7% receiving care for service-connected disabilities. These veterans are unconditionally eligible for VA care. 2. There were 8.6% with service-connected compensable disabilities who were being treated for non-service-connected disabilities. These veterans are eligible for VA care if a bed is available. 3. There were 56.3% receiving care for non-service-connected disabilities. These veterans are eligible for VA care if a bed is available and they sign an affidavit certifying their inability to defray the cost of hospitalization.

During recent years, VA hospitals have been filled to an average occupancy rate of about 92% of operating beds. This is believed to be an efficient ratio but is probably about as high as should be attained. Some beds must always be kept open for scheduled admissions, transfers, and emergencies. Veterans with service-connected disabilities are invariably admitted within 24 hours of application. Others may have to be on waiting lists pending the availability of beds. At the close of fiscal year 1958, the number of eligible applicants awaiting VA hospitalization totaled 25,418. More than 60% of these were neuropsychiatric cases.

Domiciliary Care

Under the domiciliary program the Veterans Administration provides care to veterans who do not require actual hospitalization but who, affected by permanent or chronic disabilities, are unable to earn a living and are without financial resources for support. There are 17 domiciliary units with a total operating capacity slightly in excess of 17,000 beds. The medical problem among domiciliary members is of increasing concern and interest. Advancing age in the group has increased the incidence and severity of disease and disability. Developments in medical science, particularly in the field of total rehabilitation, have opened great new possibilities and obligations for adding to the comfort and productive life of these persons.

The VA Center at Wood, Wis., has made considerable progress in a pilot study of planned living programs for domiciliary members. This program provides scheduled activities for members based on their physical and mental abilities. Included in each activity plan are periods for treatment, work assignments, and recreation. The department of medicine and surgery recognizes the need for further research and development to provide all domiciliary units with the same quality of comprehensive medical care that is available to aged and chronically debilitated patients in VA hospitals.

Professional Service Activities

The large number of significant advances that have been introduced into the VA medical program since the report of 1950 have paralleled the general advance in American medicine. The VA professional services are broadly integrated with nongovernmental health services at both national and local community levels. This active exchange is a constant stimulus to professional growth and assures the veteran patient of a quality of medical care equivalent to the best available in the particular locality.

As recently as 1954, applications for admission to tuberculosis hospitals operated by the Veterans Administration far exceeded the number of available beds. Applied research in the chemotherapy of this disease has now materially reduced the demand for beds, shortened the duration of hospital stay, decreased the relapse rate, and reduced the death-discharge ratio.

The necessary bed adjustments for a declining load of tuberculous patients have been made to fully utilize the VA hospitals most favorably located, staffed, and constructed. A number of beds that were previously used for tuberculous patients have been converted for patients with nontuberculous diseases. The tuberculosis program is gradually being integrated with the internal medicine program, and pulmonary disease services are being established in selected hospitals.

Significant advances have been made in the attack on mental illness. Outstanding consultants in the fields of psychiatry, neurology, clinical psychology, nursing, and social work assist the VA staff in evaluating and developing the program of medical care for psychiatric and neurological patients. All leads relating to the cause and more effective treatment of mental disorders and neurological disease are under investigation. The Veterans Administration has made significant contributions to the medical world in evaluating the use of tranquilizing drugs in the treatment of mental illness.

The VA member-employee program has received nationwide commendation for its accomplishments. Under this program, long-term mental patients are selected to become salaried hospital employees as a step in the transition to normal work and social experiences they will encounter when discharged to their home communities.

On June 30, 1958, there were 8,049 psychiatric patients away from the hospital on trial visit, the majority of whom were under social work supervision. The number of such patients in special placements has continued to increase. Significant numbers of patients are being handled to good advantage away from hospitals in nursing and foster homes. The Day Care Clinic for psychiatric patients has recently been introduced on a limited pilot project basis and is demonstrating in VA, as it has elsewhere, an important contribution to productive and comfortable life for patients who do not require actual institutional care. VA mental hygiene clinics play an important role in averting hospitalization for many veterans.

Since World War II, the Veterans Administration has maintained a position of leadership in medical rehabilitation which has been of outstanding importance to its patients and has been followed with interest by the medical profession throughout the world. New and important techniques have been developed with particular application to psychiatric patients, blinded patients, paraplegic and quadriplegic patients, and the older long-term patients with chronic disabilities. The newer techniques are aimed at preventing further physical and mental deterioration, helping to maintain or improve mobility, and contributing to happier living. The approach is designed to help meet a growing major health problem that confronts the entire nation as well as the Veterans Administration.

It would be impractical to attempt a full listing of contributions and advances made by VA professional services during recent years. The foregoing report may serve to illustrate the type of effort that is being made in a large number of medical and paramedical service units throughout the VA system.

Education and Training Program

In 1946, a program of education and training was instituted to overcome professional deficiencies and to improve the standards of patient care. An association with the nation's medical schools began at once and through the years has extended to 93 hospitals and 72 medical schools. This program has brought to the medical care of veteran patients not only the experience and teaching ability of the faculties of the medical schools but also the eagerness, vigor, and scientific curiosity of young medical trainees. Simultaneously, the VA hospitals were developing affiliate programs with universities and colleges for trainees in nursing, dietetics, social work, psychology, occupational therapy, and other professions in the field of medical care. One of the most important factors determining the success of the VA medical program is its close integration with American medicine and related professional groups through universities and medical schools. The status and achievement of this relationship has been the subject of a recent publication.[2]

The Veterans Administration now operates 626 training programs for resident physicians and 25 graduate training programs in dentistry. The total of 2,515 VA medical residents on duty as of April 15, 1958, represented 82% of all residency appointments in the federal service and 11% of all residency appointments in the United States. In the fields of nursing, hospital administration, and the paramedical specialties, there are about 5,000 trainees each year. The coexistence of these training programs with a medical residency program produces a hospital and clinic environment beneficial to both. While providing an essential service to veterans, these programs also make a tremendous contribution to the trained medical manpower pool of the nation, especially in those areas where such manpower is in critically short supply.

The Veterans Administration is also making a valuable contribution to undergraduate medical and dental education through the sponsorship of clinical clerkships in selected hospitals. For the academic year 1957-1958, a total of 6,022 medical students representing 62 medical schools were assigned to VA hospitals.

Approximately half of the VA hospitals are located in, or near, medical centers where they benefit from the daily associations and the general stimulus of an academic atmosphere. The other hospitals, which are peripherally located, require certain special efforts to secure comparable levels of continuing education and professional growth. In addition to the more conventional form of clinical lectures and educational duty details, a program of Physician-in-Residence has been developed for the benefit of these hospitals. Under this program highly qualified clinical teachers are scheduled for visits of three to five days at each of the hospitals. These visitors spend their entire time in intimate contact with the VA staff and develop an informal, but intensive, teaching exercise around the actual professional problems of the hospital. The physician-in-residence visit has been highly successful as both a practical and an academic stimulus and in many instances appears to be a more effective method of postgraduate education than the traditional approaches.

The VA Clinical Investigator program was inaugurated in 1957 to meet the needs for selected physicians whose primary responsibility is medical research. This program has been strongly supported by the medical schools of the nation. There are 38 clinical investigators on duty during the current year. The three-year training assignment afforded under this program is designed to produce physicians who have, in addition to their fundamental medical training, the skills and interests necessary for continued advancement in clinical research and teaching.

Research Program

Major health problems of the veteran population furnish the stimuli for the VA medical research program. This program not only provides the necessary solutions to the day-to-day problems of medical care but is of benefit to the nation and its nonveteran citizens as well. In addition, many medical specialists have been attracted by the opportunities for research and have joined the staffs of VA hospitals for this reason. This has brought a high order of medical talent to the patient's bedside.

During the current year, more than 6,000 projects are being pursued in VA research laboratories. A large proportion of these are directed toward problems of aging and the chronic long-term disabilities which are of major concern to all medical service elements.

Aside from the research projects conducted in individual VA hospitals, the department of medicine and surgery has developed a method of "cooperative study" whereby a number of VA hospitals, often in collaboration with other governmental agencies and nongovernmental groups, bring together their combined facilities and focus the talents of many experienced investigators on a given problem.

One of the more spectacular achievements of group cooperative research was the development of a successful plan for the treatment of tuberculosis by chemotherapy. The plan has revolutionized the management of patients with tuberculosis, has shortened their period of hospitalization, and has materially reduced the morbidity and mortality due to this disease.

Cooperative study programs of similar type are now being conducted in 24 major clinical problems. Among these are cancer chemotherapy, chemotherapy in psychiatry, pulmonary function studies, antihypertensive agents, antibiotic resistance of staphylococci, surgery of coronary heart disease, and so on.

Summary

This brief account of the medical program of the Veterans Administration supplements the "Kracke report" of 1950 and presents some of the more recent developments in veterans' medical care. Basic responsibilities of the VA medical service are determined in terms of the known veteran population, with special attention to problems of aging and chronic long-term disabilities.

Current trends in medical practice are increasing the need for care in VA outpatient clinics supplemented by fee basis service of private physicians and dentists. The VA hospital program has been stabilized by a new administrative policy fixing the total capacity of the system at 125,000 beds. The domiciliary program is being strengthened by greater medical interest in the health and total rehabilitation problems of the member population.

The large number of improvements in the professional services of the VA program parallel the general advance in American medicine. Education and training programs in cooperation with universities and medical schools have been of vital importance in achieving the present high standards of patient care. The research program has made valuable contributions to patient care, has been an important factor in recruitment of specialized personnel, and has established itself as a highly significant unit among the health service resources of the nation.

ATYPICAL FACE PAIN

Joseph G. Rushton, M.D., Joseph A. Gibilisco, D.D.S.
and
Norman P. Goldstein, M.D., Rochester, Minn.

An attempt was made to classify 100 patients who complained of deep, poorly localized, and vaguely described facial pain but whose symptoms could not be ascribed to trigeminal neuralgia, glossopharyngeal neuralgia, postherpetic neuralgia, or obvious disease of the teeth, throat, nose, sinuses, eyes, or ears. In 53 cases the trouble was finally ascribed to psychiatric illness such as depression, hysteria, or schizophrenia. In 33 cases it was possible to identify either organic causes such as tumors or physiological disturbances such as abnormal vasodilator activity. In 14 patients neither psychiatric nor physical causes were identified and the etiology remained undetermined. Such patients should be treated conservatively, since ill-advised operations can result in grief for both patient and surgeon.

We have chosen the term "atypical face pain" to refer to an ill-defined group of conditions known by such names as "atypical facial neuralgia," "ciliary neuralgia," "facial causalgia," "sympatheticalgia," "sphenopalatine neuralgia," and "vidian neuralgia."

A succinct definition of atypical face pain is not possible, but the term must be delimited to some degree if it is to be used intelligently. In attempting this, we can best start by stating what the term *does not include. Atypical face pain does not refer* to trigeminal neuralgia, glossopharyngeal neuralgia, postherpetic neuralgia, or pains caused by obvious disease of the teeth, throat, nose, sinuses, eyes, or ears. This leaves, then, a group of conditions characterized by pain that is "deep," poorly localized, and vaguely described by the patient. The pain may be felt in regions supplied by the fifth and ninth cranial nerves and the second and third cervical nerves. The distribution of the pain is "unanatomic," in that it may involve portions of the sensory supply of two or more of these nerves and may cross the midline. In general, this pain is constant and endures for long periods, that is, weeks to years. Trigger zones are lacking. Patients often describe the pain as boring, drawing, pressing, pulling, burning, or aching.

With such a poor attempt at definition, how can we justify a presentation of this subject? "Atypical face pain" is a term like "fever" or "convulsion." It names a symptom but does not imply a definite origin or cause. Given a case of atypical face pain, what are the possibilities as far as diagnosis, etiology, and treatment are concerned?

In an attempt to answer some of these questions, we studied 100 patients initially given a diagnosis of atypical face pain who were seen by one or more of us at the Mayo Clinic in a period of 18 months. It was found possible to classify the condition in each of these 100 patients under one of three headings, namely, (1) psychogenic, (2) organic, and (3) indeterminate. This classification was not made on the basis of any preconceived notions concerning etiological factors or pathological changes. The rationale for such a classification may become clear as each of the headings is described and discussed.

Patients with Psychogenic Face Pain

The group with psychogenic face pain consisted of 53 patients who suffered from depressive reactions, conversion hysteria, or schizophrenia. Each of them complained primarily of face pain. Other symptoms suggestive of psychiatric illness were elicited after some time had been spent in talking to these patients.

The age at onset of the pain in the 46 women and 7 men varied from 12 to 70 years, the majority of patients being in the fourth and fifth decades of life. The duration of pain varied from 1 to 36 years. Only eight patients had enjoyed any remission of pain; three of these could give no reason for remission, one had pain only with her menstrual periods, and the remaining four had noted temporary relief after minor surgical procedures on the nose, sinuses, or teeth. The other patients in the group suffered from constant pain. None was addicted to the use of opiates. Sixteen of these patients could obtain partial relief from the use of mild analgesics or sedatives, but in each instance the relief was so unsatisfactory that none had become habituated to the drug giving this partial relief.

A total of 33 patients were unable to recognize any cause for their pain. The presumed causes offered by the remaining 20 patients were as fol-

lows: dental operations, 11 patients; being struck in the face by husband, 3 patients; husband's illness, "nervous breakdown," nasal operation, parotitis, infected ear, and operation on the trigeminal nerve, one each. In general, we are reluctant to use the term "psychogenic" to classify cases of face pain. In spite of this, we think its use is justified because of the unusual character of the pain, its unanatomic distribution, the prominence of symptoms indicating emotional illness, and the lack of any signs of organic derangement.

Organically Caused Face Pain

In the second group of patients the pain apparently resulted from an actual morbid anatomic change, such as neoplasm, or from obviously disturbed physiological function, as in the case of vasodilating face pain. This group included 33 patients (14 men and 19 women). These patients could be subdivided into five groups, namely, those with (1) vasodilating face pain, (2) dental disease, (3) neuritis, (4) neoplasms, and (5) miscellaneous conditions.

Vasodilating Face Pain.—Seven men and one woman had pain thought to be the result of dilatation of arteries of the face. This pain closely resembled histaminic cephalalgia, or "cluster" headache, in character, onset, and duration, but the location was sufficiently unusual to cause some difficulty in recognition. The maximal pain was in the lower portion of the face, which contrasts to the location in the usual case of histaminic cephalalgia. The attacks were relatively brief (20 minutes to 3 hours) and usually occurred several times in 24 hours. Repeated bouts of pain would trouble the patient for days or weeks at a time and then subside, to leave him free of pain for several weeks or a year. In each case, a trial injection of ergotamine tartrate relieved the pain of a typical attack.

Six of these patients came to the clinic with a diagnosis of trigeminal neuralgia. Various surgical operations had been performed on six patients to relieve the pain. These operations included extraction of teeth, operations on the nose and paranasal sinuses, injection of alcohol into or avulsion of branches of the trigeminal nerve, and decompression of the gasserian ganglion and posterior root of the trigeminal nerve. One patient had the dubious distinction of having undergone 10 separate surgical operations on his face; each was done for the purpose of relieving his pain, and each was a doleful failure.

Dental Disease.—The face pain proved to be caused by previously unrecognized dental disease in eight patients (one man and seven women). In each instance, the pain was unusual and objective evidence for dental disease was lacking during the early part of the illness. The pain was described as a constant ache in the face but not the teeth by four patients and as a severe but intermittent ache by four patients. Two patients noted that hot or cold foods or liquids would increase the pain. Spontaneous remissions of pain were noted by six of the patients. Seven of them experienced some relief with the use of ordinary analgesics.

In general, the pain was poorly localized; in no case was it localized to the offending tooth until late in the course of the illness. Physical examinations and roentgenologic studies early in the illness gave normal results. In five patients, the final diagnosis was pulpitis, and the pain was relieved by extraction of the tooth. Three patients had causalgia of the mandibular nerve after dental extraction. All efforts failed to relieve the pain.

Neuritis.—Neuritis of some portion of the trigeminal nerve was thought to be the source of pain in eight patients (four men and four women). The age at onset varied from 24 to 73 years, and the duration of the complaint varied from two months to three years. The presumed causes for the neuritis were trauma to the face in three patients, extraction of teeth in two, and insect bite on the forehead in one; no cause for the pain could be recalled by the remaining two patients. The pain was described as burning and itching, jabbing or sticking. In each instance, it was limited to the branch of the nerve that was presumed to have been injured, and each patient had a slight but definite loss of sensation in this region.

Neoplasms.—Three patients had neoplasms that caused unusual pain. Two women had suffered from face pain for five and six years, respectively, before other evidence of a tumor became apparent; each had a cylindroma, one in the parotid gland and one in the antrum. In each patient, careful and repeated examinations had failed to disclose any abnormality until late in the course of the illness. One woman had been emotionally maladjusted all her life, and her pain was considered as psychogenic for several years. In each of these two patients, the pain was deep, shooting, and boring but poorly localized. It was present constantly but varied unpredictably in severity.

The third patient with a tumor was a man who had noted a variety of aching, jabbing, and burning pains on one side of the face for a year, during which time no cause for his distress could be discovered. This pain did not resemble trigeminal neuralgia. After a year, he became aware of numbness on the painful side of his face, and diminished sensation was found on testing with a pin and cotton. A neurofibroma of the acoustic nerve was recognized and removed.

Miscellaneous Conditions.—The remaining six patients of the group with organically caused pain had a variety of conditions. The pain in each instance was unusual, as a manifestation of the presumed cause or the cause was not readily apparent. A young woman with acromegaly had pain in the right side of the face for 16 months; her discomfort resembled trigeminal neuralgia in some ways but was not typical of that condition. Sensa-

tion on the affected side of the face was diminished. Section of the sensory root of the trigeminal nerve relieved the severe stabbing pain but left her with a constant burning discomfort on the right side of the face. Two women had thyroiditis associated with severe aching in the ear, lower jaw, and neck. A woman suffered from sudden severe pain in the right eye only, with diminution but not complete loss of vision in that eye; when examined three weeks later, she was found to have temporal arteritis.

A woman had a stroke, with hemiplegia on the right and pain over the entire right side of the body. Within a few months, the pain disappeared except for "soreness" and burning of the gums, tongue, and malar region on the right side. At the time she was last seen at the clinic, this had persisted for two years. This pain was assumed to have been the result of a thalamic lesion. A 68-year-old man had suffered from symptoms of tabes dorsalis for 22 years when seen at the clinic. One year before registration, he had noted dull, steady, aching pain on both sides of the face. This was associated with bilateral subjective diminution of the sensations of touch and pain over the distribution of the trigeminal nerve.

Face Pain of Indeterminate Etiology

Patients were classed as having face pain of indeterminate etiology (five men and nine women) largely because they failed to qualify for the other two groups. In more than half of these 14 patients, the onset of pain was after the age of 50 years. The duration of pain was relatively short as compared with that in the group with psychogenic pain. The presumed causes for the pain as given by six patients included infections, injuries, and operations about the face. The remaining eight patients could not recognize any cause for the pain. In general, the pain experienced by these patients had the following characteristics: It was of shorter duration and came on later in life than was true in the other two groups. Remissions were common. The pain was made worse by maneuvers that often make "organic" pain worse, such as chewing, rubbing the face, or jarring the head. Most of these patients could gain temporary but substantial relief from ordinary analgesics. There was no reliable evidence to indicate that the pain was psychogenic, and the character of the pain suggested an organic cause.

Comment

When a physician sees a patient who complains of face pain that is atypical, what steps can he take in an attempt to solve the problem? The first and most important step is to obtain a careful and detailed history. The patient should be asked to recall his first experience with the pain and recount its exact location and character at the onset. If he has any ideas as to the cause, these should be considered, no matter how odd they may appear to be. The subsequent course of the pain should be ascertained to learn whether it was constant or intermittent. If remissions occurred, what were their frequency and duration? What seemed to bring about these remissions? When the pain was present, what would make it worse and what would relieve it? Has the pain remained constant in location and character or has it changed? What types of treatment have been employed and what were the results? What diagnoses have been made in the past? If the patient's answers to such questions are vague or evasive, this observation itself may be of value in forming some opinion as to the nature of the illness.

A careful physical examination should be done, since it may reveal some condition, such as thyroiditis, that will account for the pain. It is often necessary to carry out dental or neurological studies, as well as examinations of the eyes, ears, nose, throat, and sinuses. Roentgenograms of the skull, sinuses, teeth, cervical portion of the spinal column, and temporomandibular joints may be required. In some cases, special roentgenologic studies, such as tomography, are of value. Other laboratory tests are usually of little value, but none should be neglected if it offers a reasonable chance of shedding light on the problem. Biopsy of any suspicious mass or region is justified.

Procedures intended to relieve pain may be of value provided they can be carried out with safety. Injection of a local anesthetic agent into the painful region or into a nerve supplying that region is of value when practical. The results of a single treatment should not be relied on, particularly when the one injection relieves the pain. In some cases, the injection should be repeated, with sterile water used to test the suggestibility of the patient. Application of a solution of cocaine to painful regions in the throat or nose may relieve the pain. If relief is obtained, the procedure may be repeated, with a solution of quinine used as a control. If the pain has characteristics suggesting that it is the result of vasodilatation, it is well to try the effect of injection of histamine to induce or augment the pain or the injection of ergotamine tartrate to relieve it.

Finally, if the patient displays evidence of significant emotional disorder, psychiatric consultation is of value. As a result of such study, it may become apparent that the pain is the primary symptom of depression or a similar major psychiatric problem. The patient's emotional state occasionally is such that it causes him to exaggerate an "organic" pain which he otherwise might bear with good grace. In such cases, proper psychiatric care may so lessen the significance of the pain that it no longer presents a problem.

At this point, one may object because we have merely described a group of unusual face pains and have not described the entity of "atypical face pain." Our answer is that we believe there are many face pains which are atypical. These constitute a

lows: dental operations, 11 patients; being struck in the face by husband, 3 patients; husband's illness, "nervous breakdown," nasal operation, parotitis, infected ear, and operation on the trigeminal nerve, one each. In general, we are reluctant to use the term "psychogenic" to classify cases of face pain. In spite of this, we think its use is justified because of the unusual character of the pain, its unanatomic distribution, the prominence of symptoms indicating emotional illness, and the lack of any signs of organic derangement.

Organically Caused Face Pain

In the second group of patients the pain apparently resulted from an actual morbid anatomic change, such as neoplasm, or from obviously disturbed physiological function, as in the case of vasodilating face pain. This group included 33 patients (14 men and 19 women). These patients could be subdivided into five groups, namely, those with (1) vasodilating face pain, (2) dental disease, (3) neuritis, (4) neoplasms, and (5) miscellaneous conditions.

Vasodilating Face Pain.—Seven men and one woman had pain thought to be the result of dilatation of arteries of the face. This pain closely resembled histaminic cephalalgia, or "cluster" headache, in character, onset, and duration, but the location was sufficiently unusual to cause some difficulty in recognition. The maximal pain was in the lower portion of the face, which contrasts to the location in the usual case of histaminic cephalalgia. The attacks were relatively brief (20 minutes to 3 hours) and usually occurred several times in 24 hours. Repeated bouts of pain would trouble the patient for days or weeks at a time and then subside, to leave him free of pain for several weeks or a year. In each case, a trial injection of ergotamine tartrate relieved the pain of a typical attack.

Six of these patients came to the clinic with a diagnosis of trigeminal neuralgia. Various surgical operations had been performed on six patients to relieve the pain. These operations included extraction of teeth, operations on the nose and paranasal sinuses, injection of alcohol into or avulsion of branches of the trigeminal nerve, and decompression of the gasserian ganglion and posterior root of the trigeminal nerve. One patient had the dubious distinction of having undergone 10 separate surgical operations on his face; each was done for the purpose of relieving his pain, and each was a doleful failure.

Dental Disease.—The face pain proved to be caused by previously unrecognized dental disease in eight patients (one man and seven women). In each instance, the pain was unusual and objective evidence for dental disease was lacking during the early part of the illness. The pain was described as a constant ache in the face but not the teeth by four patients and as a severe but intermittent ache by four patients. Two patients noted that hot or cold foods or liquids would increase the pain. Spontaneous remissions of pain were noted by six of the patients. Seven of them experienced some relief with the use of ordinary analgesics.

In general, the pain was poorly localized; in no case was it localized to the offending tooth until late in the course of the illness. Physical examinations and roentgenologic studies early in the illness gave normal results. In five patients, the final diagnosis was pulpitis, and the pain was relieved by extraction of the tooth. Three patients had causalgia of the mandibular nerve after dental extraction. All efforts failed to relieve the pain.

Neuritis.—Neuritis of some portion of the trigeminal nerve was thought to be the source of pain in eight patients (four men and four women). The age at onset varied from 24 to 73 years, and the duration of the complaint varied from two months to three years. The presumed causes for the neuritis were trauma to the face in three patients, extraction of teeth in two, and insect bite on the forehead in one; no cause for the pain could be recalled by the remaining two patients. The pain was described as burning and itching, jabbing or sticking. In each instance, it was limited to the branch of the nerve that was presumed to have been injured, and each patient had a slight but definite loss of sensation in this region.

Neoplasms.—Three patients had neoplasms that caused unusual pain. Two women had suffered from face pain for five and six years, respectively, before other evidence of a tumor became apparent; each had a cylindroma, one in the parotid gland and one in the antrum. In each patient, careful and repeated examinations had failed to disclose any abnormality until late in the course of the illness. One woman had been emotionally maladjusted all her life, and her pain was considered as psychogenic for several years. In each of these two patients, the pain was deep, shooting, and boring but poorly localized. It was present constantly but varied unpredictably in severity.

The third patient with a tumor was a man who had noted a variety of aching, jabbing, and burning pains on one side of the face for a year, during which time no cause for his distress could be discovered. This pain did not resemble trigeminal neuralgia. After a year, he became aware of numbness on the painful side of his face, and diminished sensation was found on testing with a pin and cotton. A neurofibroma of the acoustic nerve was recognized and removed.

Miscellaneous Conditions.—The remaining six patients of the group with organically caused pain had a variety of conditions. The pain in each instance was unusual, as a manifestation of the presumed cause or the cause was not readily apparent. A young woman with acromegaly had pain in the right side of the face for 16 months; her discomfort resembled trigeminal neuralgia in some ways but was not typical of that condition. Sensa-

tion on the affected side of the face was diminished. Section of the sensory root of the trigeminal nerve relieved the severe stabbing pain but left her with a constant burning discomfort on the right side of the face. Two women had thyroiditis associated with severe aching in the ear, lower jaw, and neck. A woman suffered from sudden severe pain in the right eye only, with diminution but not complete loss of vision in that eye; when examined three weeks later, she was found to have temporal arteritis.

A woman had a stroke, with hemiplegia on the right and pain over the entire right side of the body. Within a few months, the pain disappeared except for "soreness" and burning of the gums, tongue, and malar region on the right side. At the time she was last seen at the clinic, this had persisted for two years. This pain was assumed to have been the result of a thalamic lesion. A 68-year-old man had suffered from symptoms of tabes dorsalis for 22 years when seen at the clinic. One year before registration, he had noted dull, steady, aching pain on both sides of the face. This was associated with bilateral subjective diminution of the sensations of touch and pain over the distribution of the trigeminal nerve.

Face Pain of Indeterminate Etiology

Patients were classed as having face pain of indeterminate etiology (five men and nine women) largely because they failed to qualify for the other two groups. In more than half of these 14 patients, the onset of pain was after the age of 50 years. The duration of pain was relatively short as compared with that in the group with psychogenic pain. The presumed causes for the pain as given by six patients included infections, injuries, and operations about the face. The remaining eight patients could not recognize any cause for the pain. In general, the pain experienced by these patients had the following characteristics: It was of shorter duration and came on later in life than was true in the other two groups. Remissions were common. The pain was made worse by maneuvers that often make "organic" pain worse, such as chewing, rubbing the face, or jarring the head. Most of these patients could gain temporary but substantial relief from ordinary analgesics. There was no reliable evidence to indicate that the pain was psychogenic, and the character of the pain suggested an organic cause.

Comment

When a physician sees a patient who complains of face pain that is atypical, what steps can he take in an attempt to solve the problem? The first and most important step is to obtain a careful and detailed history. The patient should be asked to recall his first experience with the pain and recount its exact location and character at the onset. If he has any ideas as to the cause, these should be considered, no matter how odd they may appear to be. The subsequent course of the pain should be ascertained to learn whether it was constant or intermittent. If remissions occurred, what were their frequency and duration? What seemed to bring about these remissions? When the pain was present, what would make it worse and what would relieve it? Has the pain remained constant in location and character or has it changed? What types of treatment have been employed and what were the results? What diagnoses have been made in the past? If the patient's answers to such questions are vague or evasive, this observation itself may be of value in forming some opinion as to the nature of the illness.

A careful physical examination should be done, since it may reveal some condition, such as thyroiditis, that will account for the pain. It is often necessary to carry out dental or neurological studies, as well as examinations of the eyes, ears, nose, throat, and sinuses. Roentgenograms of the skull, sinuses, teeth, cervical portion of the spinal column, and temporomandibular joints may be required. In some cases, special roentgenologic studies, such as tomography, are of value. Other laboratory tests are usually of little value, but none should be neglected if it offers a reasonable chance of shedding light on the problem. Biopsy of any suspicious mass or region is justified.

Procedures intended to relieve pain may be of value provided they can be carried out with safety. Injection of a local anesthetic agent into the painful region or into a nerve supplying that region is of value when practical. The results of a single treatment should not be relied on, particularly when the one injection relieves the pain. In some cases, the injection should be repeated, with sterile water used to test the suggestibility of the patient. Application of a solution of cocaine to painful regions in the throat or nose may relieve the pain. If relief is obtained, the procedure may be repeated, with a solution of quinine used as a control. If the pain has characteristics suggesting that it is the result of vasodilatation, it is well to try the effect of injection of histamine to induce or augment the pain or the injection of ergotamine tartrate to relieve it.

Finally, if the patient displays evidence of significant emotional disorder, psychiatric consultation is of value. As a result of such study, it may become apparent that the pain is the primary symptom of depression or a similar major psychiatric problem. The patient's emotional state occasionally is such that it causes him to exaggerate an "organic" pain which he otherwise might bear with good grace. In such cases, proper psychiatric care may so lessen the significance of the pain that it no longer presents a problem.

At this point, one may object because we have merely described a group of unusual face pains and have not described the entity of "atypical face pain." Our answer is that we believe there are many face pains which are atypical. These constitute a

lows: dental operations, 11 patients; being struck in the face by husband, 3 patients; husband's illness, "nervous breakdown," nasal operation, parotitis, infected ear, and operation on the trigeminal nerve, one each. In general, we are reluctant to use the term "psychogenic" to classify cases of face pain. In spite of this, we think its use is justified because of the unusual character of the pain, its unanatomic distribution, the prominence of symptoms indicating emotional illness, and the lack of any signs of organic derangement.

Organically Caused Face Pain

In the second group of patients the pain apparently resulted from an actual morbid anatomic change, such as neoplasm, or from obviously disturbed physiological function, as in the case of vasodilating face pain. This group included 33 patients (14 men and 19 women). These patients could be subdivided into five groups, namely, those with (1) vasodilating face pain, (2) dental disease, (3) neuritis, (4) neoplasms, and (5) miscellaneous conditions.

Vasodilating Face Pain.—Seven men and one woman had pain thought to be the result of dilatation of arteries of the face. This pain closely resembled histaminic cephalalgia, or "cluster" headache, in character, onset, and duration, but the location was sufficiently unusual to cause some difficulty in recognition. The maximal pain was in the lower portion of the face, which contrasts to the location in the usual case of histaminic cephalalgia. The attacks were relatively brief (20 minutes to 3 hours) and usually occurred several times in 24 hours. Repeated bouts of pain would trouble the patient for days or weeks at a time and then subside, to leave him free of pain for several weeks or a year. In each case, a trial injection of ergotamine tartrate relieved the pain of a typical attack.

Six of these patients came to the clinic with a diagnosis of trigeminal neuralgia. Various surgical operations had been performed on six patients to relieve the pain. These operations included extraction of teeth, operations on the nose and paranasal sinuses, injection of alcohol into or avulsion of branches of the trigeminal nerve, and decompression of the gasserian ganglion and posterior root of the trigeminal nerve. One patient had the dubious distinction of having undergone 10 separate surgical operations on his face; each was done for the purpose of relieving his pain, and each was a doleful failure.

Dental Disease.—The face pain proved to be caused by previously unrecognized dental disease in eight patients (one man and seven women). The patient's emotional state occasionally is such that it causes him to exaggerate an "organic" pain which he otherwise might bear with good grace. In such cases, proper psychiatric care may so lessen the significance of the pain that it no longer presents a problem.

At this point, one may object because we have merely described a group of unusual face pains and have not described the entity of "atypical face pain." Our answer is that we believe there are many face pains which are atypical. These constitute a

poorly defined and loosely organized group to which the term "atypical face pain" may be applied without implying that the term describes a well-defined entity. Danger exists in considering it an entity, since this would imply a common cause and its use would assume that a definite diagnosis had been made. The term should be used only as a last resort and only after careful and exhaustive efforts have been made to arrive at a better diagnosis.

When it is finally decided that a patient has atypical face pain for which no cause can be found, treatment should be of a conservative nature. Surgical operations about the face and head should be done only if it is reasonably assured that the procedure will relieve the pain, for ill-advised operations can result in grief for both patient and surgeon.

Summary

The term "atypical face pain" should be used as the name of a symptom in the same manner in which such terms as "fever" and "convulsion" are used. These pains do not have a common cause. The designation should be used only when a definite diagnosis is not possible and with the realization that surgical treatment holds little promise of aiding these patients. Cautious conservative treatment and continued observation are the best means for care of these patients.

CLINICAL NOTES

ALLERGIC REACTION TO SUCCINYLCHOLINE

Edith R. Kepes, M.D.
and
Henry Haimovici, M.D., New York

Succinylcholine (Anectine) chloride is a "depolarizing" type of muscle relaxant with action of rapid onset and short duration. It was synthesized in 1906 by Hunt and Taveau[1]; its effect on the neuromuscular junction was first described by Bovet and others[2] in 1949. Since 1950 succinylcholine has had extensive clinical trial and has been administered to thousands of patients to produce muscular relaxation for surgery. Because of its controllability and lack of side-effects, this drug has almost replaced all other muscle relaxants in anesthesia. We have administered this drug to over 10,000 patients. The patient reported on below is the first who exhibited severe allergic skin manifestations with histamine release and circulatory collapse. As no similar observations have been published to our knowledge, the following case report is presented.

Report of a Case

A 61-year-old male was admitted with the diagnosis of an abdominal aortic aneurysm. The history revealed that for about 12 years he had had repeated episodes of pain in the epigastrium and left flank with nausea and vomiting lasting one or two days. These episodes were usually controlled by analgesic injections. He underwent a cholecystectomy 10 years previously because of persisting and unexplained pain. Anesthesia for this operation was induced with nitrous oxide and ether. After this procedure, the painful episodes remained unchanged. The patient had a negative history for allergies, except for a skin rash on the face 20 years previously. The cause of this rash was never determined. It did not respond to ointments and was controlled by x-ray radiation.

The patient was a well-developed male. All findings of physical examination were unremarkable except for moderate hypertension, with blood pressure 170/100 mm. Hg, and abdominal signs. A pulsatile mass 5 in. in diameter was palpable on the left side from the costal margin to just below the umbilicus. Radiologic studies showed clear lung fields, elongation of the aorta, and sclerotic changes in the aortic knob. A plain film of the abdomen revealed a bulging mass outlined with calcium opposite L-2 and L-3; this was presumed to be an aneurysm of the abdominal aorta. A gastrointestinal x-ray series showed compression changes on the third portion of the duodenum and the antrum of the stomach, presumably secondary to an abdominal aortic aneurysm. It also revealed a deformity of the duodenal bulb secondary to peptic ulcer disease. Laboratory findings were as follows: urine, normal; hematocrit, 47%; leukocyte count, 11,400 per cubic millimeter, with 72% polymorphonuclear cells, 6% stab forms, 1% eosinophils, 10% lymphocytes, 8% monocytes, and 3% atypical cells; blood urea nitrogen, 13.1 mg. per 100 cc.; cholesterol, 241 mg. per 100 cc.; serum amylase, 43 units; and blood sugar, 92 mg. per 100 cc.

From the Department of Anesthesiology and the Peripheral Vascular Service, Surgical Division, Montefiore Hospital.

On Dec. 15, 1958, the patient was scheduled for resection of the abdominal aortic aneurysm with graft replacement. Premedication consisted of secobarbital (Seconal) sodium, 100 mg. by mouth, and meperidine (Demerol) hydrochloride, 50 mg., and atropine sulfate, 0.4 mg., intramuscularly. Preoperative blood pressure was 155/100 mm. Hg, and the pulse rate was 100 beats per minute. Anesthesia was induced with an intravenous drip of thiamylal (Surital) sodium, 0.4% in 5% dextrose in water, followed by an intravenous drip of succinylcholine, 0.1% in 5% dextrose and water. The mouth, pharynx, and larynx were sprayed with 5% cocaine, and an endotracheal tube lubricated with 1% cyclomethycaine (Surfacaine) ointment was inserted. Eight minutes after the induction, an urticarial rash appeared, starting at the chest and spreading to every part of the skin of the trunk, head, and extremities. Five minutes later the blood pressure was 70/40 mm. Hg and the pulse, 65 beats per minute. Hydrocortisone sodium succinate (Solu-Cortef), 100 mg., followed by diphenhydramine (Benadryl) hydrochloride in 20-mg. doses (total of 100 mg.), was injected intravenously. Within five minutes the blood pressure continued to drop to 50/? mm. Hg; it then gradually rose to reach preanesthesia levels after 10 minutes. The skin changes disappeared in the next few hours, but facial edema persisted for 24 hours. His temperature the next day was elevated to 100.2 F (37.8 C).

Tests to ascertain the cause of the allergic reaction were carried out. A patch test with secobarbital was negative. Intradermal tests with succinylcholine and thiamylal were considered to be negative, despite the fact that the latter drug caused a slight redness without wheal formation. Cocaine and cyclomethycaine were not tested, since it was not planned to use these drugs again.

The patient was rescheduled for surgery on Dec. 23. Preoperative medicaments were meperidine, 50 mg., and atropine, 0.4 mg. His preanesthesia blood pressure was 160/100 mm. Hg and pulse, 80 beats per minute. Anesthesia was induced with cyclopropane. Succinylcholine, 40 mg., was used for endotracheal intubation. The patient developed the same skin reaction. Hydrocortisone, 100 mg., and diphenhydramine, 50 mg., were used immediately and the blood pressure and pulse remained unchanged. The operation was once again postponed.

On Dec. 26 the patient was tested intravenously to all drugs previously used. This was carried out in the anesthesia induction room in the presence of resuscitative equipment. There were no reactions after intravenous injection of meperidine, 10 mg.; atropine, 0.1 mg.; and thiamylal, 50 mg. Succinylcholine, 0.1% intravenous drip, produced the generalized urticarial reaction after an infusion of 30 mg. The patient required assisted respiration with oxygen for about five minutes, after which his normal muscle tone returned. The rash disappeared after one hour. Other tests, such as having the patient inhale cyclopropane and scrubbing his skin with surgical soap (Septisol), were all negative.

Resection of the abdominal aortic aneurysm with graft replacement was performed three days later with cyclopropane-ether anesthesia after induction with thiamylal sodium. His course during surgery and in the postoperative period was uneventful, and he was discharged on the 16th postoperative day.

Comment

Von Dardel and Thesleff[3] found it impossible to demonstrate any histamine-freeing effect of succinylcholine. They found no bronchoconstriction, salivation, or urticaria. On the other hand, Bourne and associates[4] reported succinylcholine to be a very weak histamine liberator. They assessed this by wheal formation in the human skin and reported it to have about one-hundredth of the activity of tubocurarine.

Routine skin testing for succinylcholine in this patient was negative, thus yielding no information about his true allergic reactions. Only after intravenous administration of the drug did the patient exhibit a prompt and full picture of his allergy. This route for testing was decided on after failure of the routine skin testing, inasmuch as such drugs were and are given intravenously during anesthesia. Although the risk of this form of testing was fully appreciated by us, we nevertheless felt that use of this route was justifiable on the basis of its use on two previous occasions. This test was followed by the immediate and complete control of the untoward reaction by prompt application of all resuscitative and antihistaminic measures.

Summary

In a patient who received several drugs during the course of induction of anesthesia, an unusually severe allergic reaction occurred, with skin manifestations and shock due to histamine release. This patient was proved to be specifically allergic to succinylcholine (Anectine) chloride only. Although intracutaneous tests to the drug were negative, intravenous administration successfully identified the offending agent. It is emphasized that, when this route is used to test possible allergies to drugs, all resuscitative measures should be readily available.

SPECIAL ARTICLE

SURGERY, GENERAL AND ABDOMINAL, 1859-1959

John H. Mulholland, M.D., New York

It is a great honor to stand in the place which has been occupied by so many illustrious men over the 100 years that the Section on Surgery has existed. The names of those who contributed to the deliberations of the Section conjure up a history of surgical progress in America.

It would be difficult for me to review the musings that a survey of the transactions of the Section bring to mind. To chronicle names, dates, and subjects would be simple but dry. As the Chairman's address should be related to theme of the occasion, I have taken this opportunity to track down from records the answer to a question which has long been on my mind: How did the Section get its curious designation, "The Section on Surgery, General and Abdominal"? Why the adjectives "General" and "Abdominal"? Why the conjunction "and"? Why are the adjectives used as supplements? The search disclosed an interesting side light on the history of the Section and led to a consideration of the meanings of the word "general."

In 1859, 12 years after the founding of the American Medical Association, there were two sections formed for the discussion of medical subjects. These were the Section on Practical Medicine and Obstetrics and the Section on Surgery and Anatomy. The development of scientific sections from this beginning is in great part a splitting off from the original two bodies of segments devoted to special subjects and in lesser part to changes in names. The names were ostensibly changed because of new orientations, but this was not entirely so. Detailed deliberations about such matters were not recorded, but there is some evidence that such unscientific considerations as jealousy, pride, jurisdictional disputes, and emotions played a part.

The rise of specialization in surgery can be traced quite clearly. In 1878 the Section on Ophthalmology, Otology, and Rhinology was established. In 1910 the Section on Genito-Urinary Diseases was formed, to become simply the Section on Urology later. In 1912 the Section on Orthopedic Surgery was established, in 1916 the Section on Gastroenterology and Proctology, and in 1940 the Section on Anesthesiology. This lineage and descent begins with the original Section on Surgery and Anatomy. From the other original Section, on Practical Medicine and Obstetrics, another line stemmed. One of the segments became, in 1873, the Section on Obstetrics and Diseases of Women and Children. The evolution of this Section to the present time is described below. In 1880 the word "children" was dropped. In 1911 the name was changed to Section on Obstetrics and Gynecology and in 1912 to Section on Obstetrics, Gynecology, and Abdominal Surgery.

Abdominal Surgery

This is the first appearance of the term in which we are interested, "abdominal," and, since our interest is in its usage as of 1959, we might go into the records for more information. Unfortunately, the minutes of section meetings are composed of titles of papers, names of authors and discussants, and a few formal resolutions. Much of what must have gone on in the hallways is unrecorded. From the tone of many of these carefully worded resolutions, however, it may be inferred that flare-ups of great magnitude were taking place. For instance, at a meeting of the Section on Surgery and Anatomy held on Wednesday, May 6, 1903 (nine years before the appearance of the word "abdominal") it is recorded that Arthur Dean Bevan of Chicago made the following motion:

> That the delegates of the Section on Surgery call the attention of the House of Delegates to the fact that much surgical work such as appendicitis, gastric ulcer, typhoid perforation, and gallbladder surgery is being at the present time duplicated in two sections of this Association, and that the very important work of obstetrics is not being sufficiently emphasized. I move that it is the sense of the Section on Surgery that its interest would best be served if the surgical diseases of women were transferred to the Section on Surgery, leaving to the gynecologic section obstetrics and the diseases of the genital organs of women. I move that the Delegates of the Section of Surgery bring this matter before the House of Delegates.

The motion was duly seconded and carried. There is no record of the immediate reaction to this resolution. That there was a reaction may be surmised from an item in the minutes of the meeting of the Section on Surgery and Anatomy on July 12, 1905, at which Dr. Brayton of Indiana announced to the members that the Indiana delegation had with them the first woman operated on for gallstones and that she would be shown the next day at the Section on Obstetrics and Diseases of Women.

There is also no doubt about the feelings of one man, Dr. H. G. Wetherell, Chairman of the Section on Obstetrics and Diseases of Women, who said in

---

From the Department of Surgery, New York University College of Medicine and the Third Surgical Division, Bellevue Hospital.

Chairman's address, read before the Section on Surgery, General and Abdominal, at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 10, 1959.

his Chairman's address in 1911 that gynecologists not only had established gynecologic and obstetric surgery on a scientific basis but in abdominal surgery had blazed the way for the general surgeon. He said further, "The Section should be designated as Obstetrics, Gynecology, and Abdominal Surgery and so come into its own. . . . This would bring back to us some of those who have been lured into other pastures." He agreed that "The average gynecologic and obstetric surgeon is often an indifferent operator when working outside of his pelvic and abdominal limitations, particularly when he attempts brain surgery." The name of the Section was changed the next year and "abdominal surgery" passed to the obstetricians and gynecologists.

Much more must have gone on than the minutes disclose. The speakers at the next year's meeting of the Section on Obstetrics, Gynecology, and Abdominal Surgery included George W. Crile, W. J. Mayo, John B. Deaver, Robert C. Coffey, and John B. Murphy, speaking on such subjects as cancer of the stomach and the technique of cholecystectomy. The program of the Section on Surgery at the same meeting included papers on fractures, bone grafts, dislocations, nephritis, anesthesia, and one of special significance on "Experimental Intestinal Obstruction in Dogs, with Especial Reference to the Cause of Death and the Treatment with Large Amounts of Normal Saline." This is, of course, the classic key paper by Hartwell and Roguet, which showed that the survival time of dogs with intestinal obstruction could be extended from 48 hours to several weeks by administration of water and electrolytes.

The next officially recorded item in this contest was a resolution introduced by Dr. Fred C. Lund of Boston at the 1914 meeting of the Section on Surgery to the effect that the words "and Abdominal Surgery" be omitted from the title "Obstetrics, Gynecology, and Abdominal Surgery" and be added to form the title "Section on Surgery, General and Abdominal." The result was that the words "Abdominal Surgery" were attached to the names of both sections and remained so attached for 24 years.

Blades, in his presidential address before the American Association for Thoracic Surgery in 1958, referred to the "battle for various organs" and "raids outside [the specialist's] designated body cavity" as results of specialty board limitations and impositions. The issue seems to have fronted long before specialty boards appeared.

To continue the chronicle, in 1938 the Section on Obstetrics and Gynecology quietly, at least in official minutes, dropped the words "Abdominal Surgery" from its title. It remains with us, however, a 21-year-old vestige. It might be appropriate at this 100th anniversary to initiate a change in title which would bring us back full circle to the embracing name "Section on Surgery." Let us discard the words "and Abdominal" as a meaningless scar. The tracks back to the origin are really not pleasant to retrace. They lead through human frailties which are no less prominent today.

General Surgery

The word "general" in "general surgery" is, however, worth some discussion. It has come to have various meanings to various people, depending on usage or point of view. "General surgery," in the purest application of the word, means surgery taken as a whole or pertaining to the whole body of surgical knowledge—that is, a concept which deals with universal rather than particular aspects and relates to each and every component of surgery. In the most impure application "general surgery" has come to mean only that which the specialist leaves behind.

The disparity in these two concepts arises because one stems from a consideration of the practice of surgery, the other from the view of advancement of surgical knowledge. The utilization of a special skill in practice is dependent on the incidence of the disease which requires that skill. The generality which is widely applicable arises from thought and study and is dependent on a mind in which an idea was created.

It is true that in the 100 years of this Section's life, blocks of specialty sections have been constantly chipped off, leaving what is considered a smaller and smaller remainder. Yet the substance of general surgery, the size of the section, number of residencies, the literature, the circulation of journals, the number of societies, and the number of certified specialists and of operations performed in general surgery all have increased. How can something be partitioned into many parts and yet expand and grow bigger?

I believe such a paradox is possible because we are talking about different things. Surgery is on the one hand a job to be done, an increasingly complex job and therefore an area in which division of labor is essential. From this standpoint the job is unquestionably done more efficiently by organization into special groups based on skill in the application of technical and specific knowledge or on the extent of the need. Working divisions of the hospital staff, of certifying boards, of societies, and of scientific sections of the American Medical Association are naturally formed and developed.

On the other hand, surgery is a body of knowledge which by its very nature is imperfect; i. e., surgical operations are required because of lack of knowledge of disease. Its content is constantly changing, shifting in emphasis, eliminating, and at the same time growing. The organization of surgical thought for growth of knowledge is not a matter of division into segments for efficiency of service but quite the reverse. This development is dependent on wide encompassing reception of information from all sources into minds in which relationships between seemingly unrelated facts can be seen and organized into concepts.

The American Medical Association was founded for the purpose of considering the deplorable status of medical schools and medical education in 1847. It is understandable that reforms in organization followed the pattern of practice. Universities were not interested in medical schools. All credit for elevation of standards belongs to the practitioners who organized themselves. The better medical schools emerged as those which were formed and influenced by members of the staffs of hospitals. Departments in the medical school were created on the basis of experience with (and therefore incidence of) disease in a hospital, and what was considered basic information required for understanding those diseases. This departmental structure persists to this day and even survived the revolution in medical education carried out in Baltimore by Johns Hopkins University.

As other universities followed the pattern of Johns Hopkins and became more involved in the search for knowledge of disease, a conflict between this purpose and that of practical lessons in the arts of medicine and surgery arose. The evolution of our modern medical school is a feature of this conflict. On the one hand, efficient application of skills demands specialization; and on the other, research demands free general inquiry and breadth. In many medical schools the names of departments as established in 1847 or before persist, but not the content. Educators, on the bases of their own objectives, have changed the structure of such departments as anatomy into research centers of embryology or endocrinology. Biochemistry departments have little interest in the chemical examination of tissues and fluids of the patient; they consider these as matters for the departments of medicine and surgery. Departments of pathology in medical schools are being divorced from the traditional pathological laboratory service of the hospital. The application of pathology as a service to the practitioner is considered a postgraduate technical or specialist discipline which is immediately useful. Undergraduate teaching in pathology is directed toward trying to hunt out mechanisms of disease, whether or not there is a morphologic manifestation, and to deal with material which will be the applied knowledge of the future.

Generalities

This trend toward impressing on the mind of the undergraduate generalities which will be applicable to all of his medical thinking in the future meets one of its great obstacles in surgery. The traditional equipment for surgical action is a detailed knowledge of anatomy. Anatomy department personnel have decided that other, more catholic, matters have crowded out descriptive static information. And, much as we decry this attitude, they may be right. Is it more important for the physician of the future to know the anatomic relations of the ulnar nerve or to know the laws of enzyme activity? We would agree that it is not bad for everyone to know about the ulnar nerve and certainly very necessary for some, but knowledge of energy-producing enzyme systems is knowledge of life itself, and universally important.

New knowledge, of greater importance and universality, has continued to accumulate like nutriment in the roots of a tree. It forces what was there further up the trunk, into the branches, to the distal leaves. Growth is conspicuous in the visible aboveground structure but takes place fundamentally in the buried, unseen underground. General surgery may be considered in one respect to be like tree growth. It serves as the entering point of general knowledge to be spread through all surgical endeavor. Departments of surgery in a medical school must deal in generalities in their undergraduate responsibilities. Fundamental generalities must be established in deeper roots of biology and chemistry, and the department of surgery must establish the place of those generalities in surgical thinking.

The development of what is now everyday knowledge of fluid and electrolyte metabolism in man is an example of what I mean. We can trace back to the physicist Arrhenius (who, like this Section, was born 100 years ago) the first light about electrolytic dissociation. In someone's mind the empirically established efficacy of sodium bicarbonate solution in the treatment of cholera, which was noted in 1832 by O'Shaughnessy, was finally connected with the basic physics of solutions. This trail of ideas might have gone through the minds of physiologists, such as Starling; biochemists, such as Clark, Van Slyke, and Hastings; pediatricians such as Holt, Howland, Marriot, and Gamble; and many others down into minds seeking answers to surgical problems. The result is some approach to a universal law which is applicable generally.

It is obvious that the favored and perhaps pretentious interpretation of the word "general" in "general surgery" is universality, or the root source for all the branches. It is really a word, though, which means no more and no less than the user intends it to mean. For example, in his delightful book, "To Work in the Vineyard of Surgery," Churchill states, "There is much evidence to show that the adjective 'General' [in Massachusetts General Hospital] refers not to a wide range of human ills and ailments, as commonly supposed, but to the principle that there shall be no racial, religious, social or economic restrictions applicable to the people it serves."

There is another instance in an obituary memoir of Dallas B. Phemister, published in the *Transactions of the American Surgical Association* for 1952. The concluding sentence is, "It might well be said that he was one of the last of the great general surgeons." This implied, I think, that Phemister's interests were spread out and that he involved himself in all surgical activities. While I agree with the designation "great general surgeon," I believe it applies to him because he had depth rather than width of interests. His search into mechanisms was so profound that what he said and wrote was of general importance. That he was not the last is attested by the career of one of his great pupils, whose interests are listed in "American Men of Science" as "calcium metabolism, sex hormones, cancer, enzymes of the blood, and bone physiology." The depth of these interests has resulted in advancing all surgical knowledge useful to the gynecologist, urologist, orthopedist, and general surgeon alike.

This Section on Surgery is a forum for the dissemination of surgical knowledge. It is distinct from other forums in that for 100 years its purpose has been to join the minds of those whose job it is to dig for information with the minds of those whose job it is to use the information intelligently. There is little of the ritualistic exclusiveness of other surgical societies in its membership. Somewhere along the line it acquired an invidious name, as a result of differences in opinion among those who were performing the ultimate task of utilizing knowledge. For a time the Section identified itself more with the utilitarian aspect and became involved in quarrels about jurisdictional rights and practicing privileges. This is understandable, because surgery is so much a matter of utilizing knowledge directly and by specific action. More farsighted is the later and modern identification of its bonds to the other end of the production line. The next 100 years will see expansion of the content of knowledge and responsibility for its application beyond any experience in history. May the Section on Surgery, which I hope it will be called, expand in like fashion.

550 First Ave. (16).

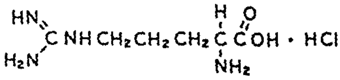
COUNCIL ON DRUGS

NEW AND NONOFFICIAL DRUGS

The following descriptions of drugs are based on available evidence and do not in any case imply endorsement by the Council.

H. D. Kautz, M.D., *Secretary*.

Arginine Hydrochloride (Argivene).—L-Arginine hydrochloride.—The structural formula of arginine hydrochloride may be represented as follows:



$$\begin{matrix}HN\\H_2N\end{matrix}\!\!>C\,NH\,CH_2CH_2CH_2\underset{NH_2}{\overset{H}{C}}\overset{O}{C}OH\cdot HCl$$

Actions and Uses.—Arginine hydrochloride is an amino acid preparation with pharmacological actions and clinical uses similar to those of sodium glutamate. (See the monograph on sodium glutamate in New and Nonofficial Drugs.) Its intravenous administration causes a lowering of blood ammonia levels. This effect is of very limited usefulness for the symptomatic management of gravely ill patients with encephalopathies associated with ammoniacal azotemia, usually the result of severe liver dysfunction (so-called hepatic coma). Although the drug has no effect on the course of the liver disease itself, its ability to lower blood ammonia levels may bring about a reversion of the neurological status from stupor to consciousness. As in the case of sodium glutamate, symptomatic improvement with arginine hydrochloride seems to be most pronounced in those patients whose comatose condition has been precipitated by circulatory nitrogenous loads of exogenous origin. The proper management of hepatic encephalopathies with hyperammoniemia includes a low-protein intake, antibiotics given orally, evacuation of the gastrointestinal tract, and dextrose infusions. Hence, the intravenous use of arginine hydrochloride in such cases is considered an adjunct to other measures designed to lower blood ammonia levels.

Ammoniemia is sometimes observed in such other conditions as congestive heart failure, severe infections, anoxic states, shock, certain types of poisoning, metabolic acidosis (including diabetic coma) and erythroblastosis fetalis. It is doubtful, however, that these conditions are positive indications for arginine infusions.

Arginine hydrochloride is sodium-free and, hence, is better tolerated than equivalent amounts of sodium glutamate. The chief hazard to its use is associated with the presence of the chloride ion in the salt. Thus, the drug should be used with caution in patients with hyperchloremic acidosis, especially in the presence of renal disease or anuria.

Dosage.—Arginine hydrochloride is administered intravenously. A solution containing 20 Gm. of the drug in 50 cc. of water is diluted with 500 to 1,000 cc. of 5 to 10% dextrose in water for injection. This diluted solution is then infused by intravenous drip over a period of four hours.

Preparations.—solution (injection) 20 Gm. in 50 cc.

Year of introduction: 1957.

Gray Pharmaceutical Company, Inc., cooperated by furnishing scientific data to aid in the evaluation of arginine hydrochloride.

EXTERNAL AND MIDDLE EAR INFECTIONS

INFECTION of the external auditory canal and chronic infection of the middle ear that has failed to resolve comprise two widely encountered clinical entities. In the case of the former, external otitis constitutes anywhere from 5 to 40% of all ear infections seen in the United States, the wide variation being due to regional and sectional differences in atmospheric temperature and humidity.

Judicious selection of medicaments for the treatment of external otitis, the more common types of which include furunculosis, otomycosis, and eczematous dermatitis, often depends on the bacteriology of the infectious process. The causative agent of external otitis can be any one of a number of gram-positive or gram-negative bacteria and fungi. In troublesome cases, antibiotic sensitivity tests can aid in the selection of the most effective antimicrobial drugs for use in therapy. These tests, however, are not foolproof, and their interpretation requires experience and judgment for proper evaluation.

Until fairly recently little attention was paid either to the pH of the skin of the external auditory canal or to the pH of solutions applied to it. In a series of investigations, Fabricant and Perlstein[1] have pointed out that the pH of solutions applied to the skin of the external auditory canal is an important factor in therapy. It is not uncommon to find that the difference in effectiveness of two apparently similar agents is due to the ability of one medicament to produce or enhance a state of acidity, while the other produces or enhances a state of alkalinity that is unphysiologic and provides fertile soil for the propagation of infection. Once there is interruption of the continuity of the epithelial lining and an alteration of the pH from the acid to the alkaline side, bacteria and fungi have their greatest opportunity for growth and multiplication. These properties are enhanced by the use of solutions in the external auditory canal whose pH is alkaline.

Susceptibility to infection by bacteria is widely held to be due to the removal of the antibacterial "acid mantle" and its displacement by an abnormal "alkaline mantle." This phenomenon is especially applicable to the external auditory canal, which by virtue of its exposed position to the outside world is subject to dermatological lesions, traumatic and clinical indignities, and invasion by a host of micro-organisms. Here, a moist environment containing cellular detritus and cerumen frequently serves as an adequate culture medium for the growth of bacteria and fungi.

The seborrheic areas of the body are generally more alkaline than other parts of the skin's surface. Alkaline areas are less bactericidal than the rest of the skin and consequently are predisposed to infection. Measurements of the pH of the skin of the external auditory canal, clinically normal, produced pH values chiefly within the acid range. Measurements of the pH of the skin in external otitis, by Fabricant,[1b] showed the pH range in men to be from 7.1 to 7.8 and in women to be from 7.1 to 7.4.

Various topical bactericidal otic solutions have been introduced in recent years for the treatment of external otitis and chronic suppurative otitis media. Many of them have a useful place in contemporary practice. In many instances the clinical response is satisfactory, yet enough failures exist to make the physician aware of the truth of the old adage "sometimes they work and sometimes they don't." In troublesome cases of chronic suppurative otitis media it is always worth considering the systemic use of antibiotics and sulfonamides. From time to time surprisingly favorable responses are obtained, to the delight of the patient who has almost given up hope and the prescribing physician who also has begun to despair. While bacteriological studies and sensitivity tests frequently assist in the choice of appropriate medication, neither studies nor tests guarantee the drying of the discharge from a chronically infected middle ear cavity. The drying of the ear itself holds the secret of success or failure.

ORGANIZATION SECTION

REPORT OF THE SECTIONS OF THE SCIENTIFIC ASSEMBLY

ATLANTIC CITY MEETING, JUNE 8-12, 1959

SECTION ON ANESTHESIOLOGY

The Section on Anesthesiology held its first meeting on Wednesday morning, June 10, in the Ballroom of the Shelburne Hotel. On Thursday morning, June 11, it met jointly with six other Sections in a symposium on childbirth, in the Ballroom of Convention Hall and on Thursday afternoon jointly with the Section on Nervous and Mental Diseases in a symposium on hypnosis in Room D, Convention Hall. The final meeting was held on Friday morning, June 12, in the Ballroom of the Shelburne Hotel. In addition to the joint meetings 14 papers were presented, 7 of which were included in a symposium on complications of anesthesia.

At the business meeting on Wednesday, June 10, reports were given by the Secretary, the representative to the American Board of Anesthesiology and the Section Delegate. Members of the Section who participated in the Scientific Exhibit were presented.

Two resolutions were passed. The first was in opposition to a third year in training in anesthesiology and was directed to the Council on Medical Education and Hospitals. The second resolution approved mouth-to-mouth breathing in resuscitation.

At the business meeting on Friday, June 12, the following officers were elected: Chairman, Dr. Meyer Saklad, Providence, R. I., and Vice-chairman, Dr. Alice McNeal, Birmingham, Ala. The Secretary, Dr. Vincent J. Collins, New York, and the Assistant Secretary, Dr. Kenneth K. Keown, Columbia, Mo., were continued in their terms expiring in 1961. The Delegate, Dr. Joseph H. Failing, Los Angeles; the Alternate Delegate, Dr. Ralph Sappenfield, Miami, Fla., and the Representative to the Scientific Exhibit, Dr. Edwin L. Rushia, Augusta, Ga., were continued until 1960.

The Section sponsored six scientific exhibits, of which one received a certificate of merit, one an honorable mention, and one a certificate of appreciation.

SECTION ON DERMATOLOGY

The Section on Dermatology met in Convention Hall, Room A, on Wednesday, Thursday, and Friday mornings, June 10, 11, and 12. Sixteen papers were presented in addition to a panel discussion on corticosteroid therapy in dermatology.

At the business meeting on Friday, June 12, the following officers were elected: Chairman, Dr. Wiley M. Sams, Miami, Fla.; Vice-chairman, Dr. William J. Morginson, Salt Lake City, Utah; Secretary, Dr. Edward P. Cawley, Charlottesville, Va.; Asst. Secretary, Dr. Harry L. Arnold, Jr., Honolulu, Hawaii; Delegate, Dr. Winfred A. Showman, Tulsa, Okla.; Alternate Delegate, Dr. Maurice J. Costello, New York; Representative to the Scientific Exhibit, Dr. Stanley E. Huff, Evanston, Ill. It was also voted that Dr. Beatrice M. Kesten, New York, be designated as a representative of the Section on Dermatology to the American Board of Dermatology, and Dr. J. Walter Wilson, Los Angeles, the representative of the Section to the International Congress on Dermatology which meets in the United States in 1962.

The Section sponsored 15 exhibits in the Scientific Exhibit. There were three awards, one a certificate of merit and two honorable mentions. In addition, a certificate of merit was awarded for medical photography in one of the exhibits.

SECTION ON DISEASES OF THE CHEST

The Section on Diseases of the Chest met four times, three of them in joint session. On Tuesday afternoon, June 9, in Borton Hall, Dennis Hotel, a joint session was held with the Section of Gastroenterology and Proctology and the Section on Radiology on esophageal hiatal hernia. On Wednesday afternoon, June 10, there was a symposium on pneumoconiosis with the Section on Preventive Medicine. On Thursday morning, June 11, the Section participated in the symposium on childbirth with six other Sections. The final meeting was held in Borton Hall, Dennis Hotel, where nine papers and two panel discussions were presented.

At the business meeting on Friday, June 12, the following officers were elected: Chairman, Dr. Seymour M. Farber, San Francisco; Vice-chairman, Dr. Herman J. Moersch, Rochester, Minn.; Secretary, Dr. Burgess L. Gordon, Albuquerque, N. Mex.; Delegate, Dr. J. Winthrop Peabody, Sr., Washington, D. C.; Representative to the Scientific Exhibit, Dr. Edwin R. Levine, Chicago.

The Section sponsored seventeen exhibits in the Scientific Exhibit, of which one received a certificate of merit and one an honorable mention. The Section also sponsored the Special Exhibit on Pulmonary Function.

SECTION ON EXPERIMENTAL MEDICINE AND THERAPEUTICS

The Section on Experimental Medicine and Therapeutics held its first meeting Tuesday afternoon, June 9, in Ritz Hall, Ritz Carlton Hotel. In addition to the Chairman's Address and the George Minot Lecture, there was a symposium on the direct relief of coronary occlusion. On Wednesday morning, June 10, this Section joined with five other Sections for the symposium on hepatic diseases. On Thursday afternoon, June 11, there was a joint meeting with the Section on Internal Medicine in the Ballroom, Convention Hall, with a symposium on coronary disease.

The Section observed its centennial at Atlantic City, N. J., the guest speaker being Dr. J. N. Morris of London.

At the business meeting on Tuesday, June 9, the following officers were elected: Chairman, Dr. Jack D. Myers, Pittsburgh; Vice-chairman, Dr. Elliot V. Newman, Nashville, Tenn.; Secretary, Dr. Samuel P. Martin, Gainesville, Fla.; Delegate, Dr. Harry F. Dowling, Chicago; and Representative to the Scientific Exhibit, Dr. Joseph F. Ross, Los Angeles.

The Section sponsored 29 exhibits in the Scientific Exhibit. There were four awards, the Hektoen Silver Medal, one certificate of appreciation, and two honorable mentions. In addition, there was an honorable mention for medical photography in one of the exhibits.

SECTION ON GASTROENTEROLOGY AND PROCTOLOGY

The Section on Gastroenterology and Proctology held four meetings, three of them jointly with other Sections. On Tuesday afternoon, June 9, it joined with the Sections on Diseases of the Chest and Radiology for a symposium on esophageal hiatal hernia, Borton Hall, Dennis Hotel. On Wednesday morning, June 10, there was a symposium on gastric cancer with the Sections on Radiology and Pathology and Physiology in Trimble Hall, Claridge Hotel. On Wednesday afternoon the Section joined with five other Sections in the symposium on hepatic diseases. The final meeting was held on Thursday morning, June 11, in Trimble Hall, Claridge Hotel, when four papers were presented and followed by a panel discussion on steatorrhea.

At the business meeting on Thursday, June 11, the following officers were elected: Chairman, Dr. Joseph B. Kirsner, Chicago; Vice-chairman, Dr. William H. Dearing, Rochester, Minn.; Secretary, Dr. Gordon McHardy, New Orleans; Delegate, Dr. Stuart T. Ross, Garden City, N. Y.; Alternate Delegate, Dr. Neil Swinton, Boston; Representatives to the Scientific Exhibit, Dr. Thomas E. Machella, Philadelphia, and Dr. Willard Bernhoft, Buffalo.

Sixteen exhibits in the Scientific Exhibit were sponsored by the Section. Of four awards presented, one was a certificate of merit, one a certificate of appreciation, and two honorable mentions. In addition, an honorable mention was awarded for medical illustration in one of the exhibits.

SECTION ON GENERAL PRACTICE

The Section on General Practice met four times, three being joint meetings with other Sections. All meetings were held in the Ballroom, Convention Hall. The first meeting was Tuesday afternoon, June 9, when eleven papers were presented, five of which composed a symposium on viruses. On Wednesday afternoon, June 10, the Section joined with five other Sections in the symposium on hepatic diseases, and on Thursday morning, June 11, it participated in the symposium on childbirth with six other Sections. On Friday morning, June 12, a symposium on athletic injuries was held with the Sections on Orthopedic Surgery and Physical Medicine.

At the business meeting on Tuesday, June 9, the following officers were elected: Chairman, Dr. Robert L. Crawford, Lancaster, S. C.; Vice-chairman, Dr. Charles Alvey, Muncie, Ind.; Secretary, Dr. E. I. Baumgartner, Oakland, Md.; Representative to the Scientific Exhibit, Dr. I. Phillips Frohman, Washington, D. C.; Delegate, Dr. Lester D. Bibler, Indianapolis; Alternate Delegate, Dr. Milton Casebolt, Kansas City, Mo. Dr. Charles McArthur was reappointed as Chairman of the committee in charge of physical examinations for physicians.

The Section sponsored 24 exhibits in the Scientific Exhibit. There were three awards, consisting of the Billings Bronze Medal, a certificate of merit, and an honorable mention. The Section also sponsored "A P. E. For Every M.D." promoting annual physical examinations for physicians. In Atlantic City 1,037 electrocardiograms were made of which approximately 23% were abnormal or borderline cases. This was considerably higher than in previous years when the figure was about 18%. Of 802 chest x-rays made, about 18% showed abnormality. There were 60 tuberculosis suspects, 28 cardiovascular abnormalities, and 43 other chest conditions.

SECTION ON INTERNAL MEDICINE

The Section on Internal Medicine met four times, twice in joint meetings with other Sections. At the first meeting on Wednesday morning, June 10, in the Ballroom, Convention Hall, four papers were presented, including the Billings Lecture, followed by a panel discussion on intractable angina pectoris. On Wednesday afternoon, the Section joined five other Sections in the symposium on hepatic diseases. On Thursday morning, June 11, the Section met in Ritz Hall, Ritz Carlton Hotel, where four papers were presented, together with a panel discussion on the etiology of infections. The final meeting in the Ballroom, Convention Hall, on Thursday afternoon, June 11, was a symposium on coronary disease with the Section on Experimental Medicine and Therapeutics. The Chairman devoted his address to "The Endeavor of Internal Medicine, 1859-1959," since this was the centennial meeting of the Section.

At the business meeting on Thursday, June 11, the following officers were elected: Chairman, Dr. R. H. Kampmeier, Nashville, Tenn.; Vice-chairman, Dr. George T. Harrell Jr., Gainesville, Fla.; Secretary, Dr. Wright R. Adams, Chicago; Delegate, Dr. Charles T. Stone Sr., Galveston, Texas; Alternate Delegate, Dr. Carter Smith, Atlanta, Ga.; and Representative to the Scientific Exhibit, Dr. Henry T. Ricketts, Chicago.

The Section sponsored 22 exhibits in the Scientific Exhibit, of which one received a certificate of merit and two honorable mentions.

SECTION ON LARYNGOLOGY, OTOLOGY, AND RHINOLOGY

The Section on Laryngology, Otology, and Rhinology met three times in the St. Dennis Room, Dennis Hotel, on Tuesday, Wednesday, and Thursday afternoons, June 9, 10, and 11. Twenty papers were read, including that of the guest of honor, Dr. George M. Coates, Philadelphia.

At the business meeting on Tuesday, June 9, reports were heard from the Section Delegate and the Section Representative to the Board of Governors of the American College of Surgeons. A resolution was passed, urging that audiograms be included in the physical examinations of physicians at the annual meeting.

The following officers were elected: Chairman, Dr. Paul H. Holinger, Chicago; Vice-chairman, Dr. Lawrence R. Boies, Minneapolis; Secretary, Dr. Walter E. Heck, San Francisco; Delegate, Dr. Gordon F. Harkness, Davenport, Iowa; Alternate Delegate, Dr. Dean Lierle, Iowa City, Iowa; Representative to the Scientific Exhibit, Dr. Walter H. Maloney, Cleveland.

In the Scientific Exhibit, the Section sponsored nine exhibits, of which one was awarded the Billings Gold Medal, one a certificate of merit, and one an honorable mention.

SECTION ON MILITARY MEDICINE

The Section on Military Medicine met three times on Tuesday, Wednesday, and Thursday afternoons, June 9, 10, and 11 in Room A, Convention Hall. Ten papers were presented in addition to three panel discussions and a symposium. A new feature of the program was initiated at this meeting, consisting of audio-visual presentations in conjunction with the papers.

At the business meeting on Tuesday, June 9, the following officers were elected: Chairman, Dr. George H. Houck, Palo Alto, Calif.; Vice-chairman, Dr. James H. Kidder, Washington, D. C.; Secretary, Dr. James T. McGibony, Washington, D. C.; Delegate, Dr. Alphonse McMahon, St. Louis, Mo.; Alternate Delegate, Dr. Charles L. Leedham, Cleveland; Representative to the Scientific Exhibit, Dr. Frank M. Townsend, Washington, D. C.

The Section sponsored 16 exhibits in the Scientific Exhibit. There were two awards, one certificate of merit and one honorable mention.

Point credit was given to active and reserve officers of the Air Force, Army, and Navy for attendance at the meeting.

SECTION ON NERVOUS AND MENTAL DISEASES

The Section on Nervous and Mental Diseases met five times, two of them jointly with other Sections. On Tuesday afternoon, Wednesday morning, and Wednesday afternoon, June 9 and 10, the Section met in Room D, Convention Hall, papers being devoted to the three branches of the Section—neurology, psychiatry, and neurosurgery. On Thursday morning, June 11, the Section participated with six other Sections in the symposium on childbirth, and on Thursday afternoon with the Section on Anesthesiology in a symposium on hypnosis. In addition to joint meetings, 18 papers were presented.

At the business meeting on Wednesday morning, June 10, the following officers were elected: Chairman, Dr. E. S. Gurdjian, Detroit; Vice-chairman, Dr. William T. Lhamon, Houston, Texas; Secretary, Dr. Howard P. Rome, Rochester, Minn.; Delegate, Dr. Francis M. Forster, Madison, Wis.; Alternate Delegate, Dr. Karl O. Von Hagen, Los Angeles; Representative to the Scientific Exhibit, Dr. Benjamin Boshes, Chicago. Dr. Alexander Ross, Indianapolis, and Dr. Jacques Gottlieb, Detroit, were nominated for Director of the American Board of Psychiatry and Neurology.

The Section sponsored 13 exhibits in the Scientific Exhibit, one of which was awarded the Billings Silver Medal and one a certificate of merit.

The 1959 meeting was the centennial of the Section. It was observed by a centennial address of the Chairman on psychotherapy and a special exhibit showing the progress of the Section during the last 100 years.

SECTION ON OBSTETRICS AND GYNECOLOGY

The Section on Obstetrics and Gynecology met three times, once alone and twice jointly with other Sections. At the first meeting on Wednesday morning, June 10, held in Ritz Hall, Ritz Carlton Hotel, three papers and a panel discussion on pelvic exenteration were presented. The Section joined with six other Sections on Thursday morning, June 11, for the symposium on childbirth, and on Friday morning with the Section on Pathology and Physiology for panel discussions on erythroblastosis fetalis or hemolytic disease of the newborn and on ovarian tumors.

The centennial of the Section was observed by a commemorative luncheon on Wednesday, June 10, with Professor Andrew Claye, Leeds, England, President of the Royal College of Obstetricians and Gynecologists, as the guest speaker.

At the business meeting, on June 10, the following officers were elected: Chairman, Dr. Curtis Lund, Rochester, N. Y.; Vice-chairman, Dr. H. Close Hesseltine, Chicago; Secretary, Dr. Keith P. Russell, Los Angeles; Delegate, Dr. Ralph E. Campbell, Madison, Wis.; Alternate Delegate, Dr. Roy J. Heffernan, Brookline, Mass.; and Representative to the Scientific Exhibit, Dr. Frederick H. Falls, Oak Park, Ill. The Section Delegate gave a report followed by a discussion of the Section's relationship and participation in the functions of the Joint Commission on Accreditation of Hospitals and in the proposed General Practice Training Program under consideration by the House of Delegates.

The Section sponsored 23 exhibits in the Scientific Exhibit, one of which received a certificate of merit and one an honorable mention.

SECTION ON OPHTHALMOLOGY

The Section on Ophthalmology met in the Renaissance Room of the Ambassador Hotel on Wednesday, Thursday, and Friday mornings, June 10, 11, and 12. Twenty-three papers were presented, including the address of the invited foreign guest, Dr. S. P. Meadows, London. The Association for Research in Ophthalmology met under the auspices of the Section on Ophthalmology on Tuesday, Wednesday, and Thursday afternoons, June 9, 10, and 11, when 24 papers were presented.

At the business meeting on Thursday, June 11, the following resolution was passed:

> WHEREAS, Glaucoma is a leading cause of irreversible blindness in adults in the United States; and
>
> WHEREAS, The National Medical Foundation for Eye Care has introduced a Glaucoma Identification Card which will identify glaucoma patients to all attending physicians in any circumstance, especially in emergency, and thus facilitate the continuity of medical care which is essential in the management of the disease and the prevention of blindness from this cause; therefore be it
>
> *Resolved*, That the attention of the members of the medical profession be directed to the Glaucoma Identification Card which will make immediately available to all attending physicians information concerning the patient's use of and requirement for miotics and other medications.

Reports of the following representatives from the Section were accepted and submitted to the Board of Trustees for approval:

American Committee on Optics and Visual Physiology
American Board of Ophthalmology
National Registry of Ophthalmic Pathology
Scientific Exhibit
National Conference on Medical Nomenclature
College of Surgeons, Board of Governors
American Orthoptic Council
Lucian Howe Fund
Research in Ophthalmology and Blindness
Delegate to House of Delegates
Program Committee

The Executive Committee recommended that the Committee on Museum of Ophthalmic History be continued for one more year.

The following appointments, recommended by the Executive Committee, were approved by the Section:

Dr. Arthur Linksz reappointed to the American Committee on Optics and Visual Physiology; Dr. A. Edward Maumenee appointed to the American Board of Ophthalmology; Dr. A. B. Reese reappointed to the National Registry of Ophthalmic Pathology; Dr. Derrick Vail reappointed delegate and Dr. W. Guernsey Frey, alternate delegate, to the International Federation of Ophthalmic Societies; Dr. Robert Laughlin reappointed to the American Orthoptic Council; Drs. A. D. Ruedemann and Michael J. Hogan reappointed to the National Committee for Research in Ophthalmology and Blindness; Dr. James H. Allen reappointed delegate to the Pan American Congress of Ophthalmology; Drs. Burton Chance, Hans Barkan and Frederick C. Cordes reappointed as representatives to the Museum of Ophthalmic History; Dr. Conrad Berens reappointed as representative to the National Conference on Medical Nomenclature; Drs. Ramon Castraviego and Phinizy Calhoun reappointed to the Committee on Eye Banks, and Drs. Harold F. Falls, William F. Hughes Jr., Albert N. Lemoine Jr., Kenneth C. Swan, Michael J. Hogan, and Bernard Becker reappointed and Drs. Edward W. D. Norton and DuPont Guerry III appointed to the Program Committee.

The Section nominated three members, Drs. S. Rodman Irvine, Ralph W. Danielson, and Ralph O. Rychener for selection of one to serve on the Board of Governors of the American College of Surgeons for the term 1960 to 1963.

The Section submitted the names of Drs. Arthur Gerard DeVoe, Angus MacLean, and Ralph O. Rychener as nominees from the Section for selection of one to serve on the Advisory Council of the American College of Surgeons.

The $250 prize for the best exhibit was awarded to Drs. Gilbert Baum and Ivan Greenwood for their exhibit "Application of Ultrasonic Locating Techniques to Ophthalmology."

The $250 prize for the best paper was awarded to Drs. Thomas P. Kearns, Robert M. Salassa, Collin S. MacCarth, and James W. Kernohan for their paper "Ocular Manifestations of Pituitary Tumor in Cushing's Syndrome," judged on the basis of presentation and originality.

The Prize Medal in Ophthalmology was awarded to Dr. Francis Heed Adler for his many contributions to the specialty.

At the business meeting, the following Section officers were elected: Chairman, Dr. Harold G. Scheie, Philadelphia; Vice-chairman, Dr. Paul A. Chandler, Boston; Secretary, Dr. Henry F. Allen, Boston; and Representative to the Scientific Exhibit, Dr. Frank W. Newell, Chicago; Committee on the Award of the Knapp Medal: Drs. Arthur Bedell, Chairman; A. D. Ruedemann and James H. Allen.

The Section sponsored 14 exhibits in the Scientific Exhibit, to which several awards were given. In addition to one certificate of merit and two honorable mentions, the Section award of $250 was made to Drs. Gilbert Baum and

Ivan Greenwood as noted above. A certificate of merit was given to a medical illustrator for the outstanding illustration in one of the scientific exhibits in this Section.

SECTION ON ORTHOPEDIC SURGERY

The Section on Orthopedic Surgery held three meetings, one being a joint session. At the meeting on Wednesday morning, June 10, in Kerry Hall, Shelburne Hotel, seven papers were presented, and on Thursday morning, June 11, six papers were presented. On Friday morning, June 12, in the Ballroom of Convention Hall, a symposium on athletic injuries was presented jointly with the Sections on General Practice and Physical Medicine.

At the business meeting on Wednesday, June 10, the report of the Section Delegate, Dr. H. Relton McCarroll, was received. On Thursday, June 11, the following officers were elected: Chairman, Dr. H. Herman Young, Rochester, Minn.; Vice-chairman, Dr. James Vernon Luck, Los Angeles; Secretary, Dr. Robert J. Joplin, Brookline, Mass.; Asst. Secretary, Dr. John C. Wilson Jr., Los Angeles; Delegate, Dr. Edward L. Compere, Chicago; Alternate Delegate, Dr. Harry R. Walker, Oakland, Calif.; Representative to the Scientific Exhibit, Dr. James I. Kendrick, Cleveland; and Assistant Representative to the Scientific Exhibit, Dr. Ernest Burke Evans, Galveston, Texas; Representatives to the American Board of Orthopedic Surgery, Dr. David S. Grice, Philadelphia, and Dr. Edwin R. Schottstaedt, San Francisco. The Section did not name any alternates for the two representatives to the American Board of Orthopedic Surgery.

The Section sponsored 22 exhibits in the Scientific Exhibit, of which one received a certificate of merit and one an honorable mention.

SECTION ON PATHOLOGY AND PHYSIOLOGY

The Section on Pathology and Physiology held four meetings, including three joint sessions. On Wednesday morning, June 10, there was a joint session with the Section on Radiology in Trimble Hall, Claridge Hotel, with a symposium and panel discussion on gastric cancer. On Wednesday afternoon, the Section participated with five other Sections in the symposium and panel discussion on hepatic diseases. On Thursday morning, June 11, the Section met in the Ballroom, Shelburne Hotel, where seven papers were presented. The final meeting on Friday, June 12, was held with the Section on Obstetrics and Gynecology, and presented panel discussions on erythroblastosis fetalis and on ovarian tumors.

The Section celebrated 100 years of physiology, the guest speaker being Dr. R. R. A. Coombs, Cambridge, England.

At the business meeting on Thursday, June 11, the Section passed a resolution urging the Council on Scientific Assembly to continue exploration of the possible establishment of an exhibit in clinical pathology of practical scope. A report from the Section Delegate was received.

The following officers were elected: Chairman, Dr. Russell L. Holman, New Orleans; Vice-chairman, Dr. Lester R. Dragstedt, Chicago; Secretary, Dr. Hugh E. Edmondson, Los Angeles; Delegate, Dr. Lall G. Montgomery, Muncie, Indiana; and Representative to the Scientific Exhibit, Dr. Edwin R. Levinson, Chicago.

The Section sponsored 13 exhibits in the Scientific Exhibit. There were two awards, one certificate of merit and one honorable mention. In addition, the Section sponsored the special exhibit on fresh tissue pathology.

SECTION ON PEDIATRICS

The Section on Pediatrics held three meetings, two of which were joint sessions with other Sections. At the first meeting on Tuesday afternoon in the Ballroom, Shelburne Hotel, eight papers were presented. On Wednesday afternoon, June 10, a joint session was held with the Section on Urology in Ritz Hall, Ritz Carlton Hotel, when six papers were read. The Section joined with six other Sections on Thursday morning, June 11, for the symposium on childbirth.

At the business meeting on Tuesday, June 9, it was voted to approve the brochure "Care of Children in Hospitals," prepared by the American Academy of Pediatrics. The Section endorsed the First International Conference on Mental Retardation to be held in Portland, Maine, on July 27-31, 1959. The report of the Custodian of the Jacobi Fund was approved.

The following officers were elected: Chairman, Dr. Clement A. Smith, Boston; Vice-chairman, Dr. Robert Grayson, Miami Beach, Fla.; Secretary, Dr. Arild E. Hansen, Galveston, Texas; Delegate, Dr. Walter B. Stewart, Atlantic City, N. J.; and Representative to the Scientific Exhibit, Dr. F. Thomas Mitchell, Memphis, Tenn.

The Section sponsored 20 exhibits in the Scientific Exhibit. Three exhibits received awards, consisting of the Hektoen Bronze Medal, a certificate of merit, and an honorable mention.

SECTION ON PHYSICAL MEDICINE

The Section on Physical Medicine met four times, once jointly with another Section. At the first three meetings in Kerry Hall, Shelburne Hotel, on Tuesday, Wednesday, and Thursday afternoons, June 9, 10, and 11, fourteen papers were presented in addition to a panel discussion on overwork of the neuromuscular mechanism by therapeutic and/or other exercise. The last meeting on Friday morning, June 12, in the Ballroom, Convention Hall, was a symposium on athletic injuries with the Sections on General Practice and Orthopedic Surgery.

At the business meeting on Wednesday, June 10, the following officers were elected: Chairman, Dr. Lewis A. Leavitt, Houston, Texas; Vice-chairman, Dr. James W. Rae, Ann Arbor, Mich.; Secretary, Dr. Earl C. Elkins, Rochester, Minn.; Delegate, Dr. Walter J. Zeiter, Cleveland; Alternate Delegate, Dr. A. B. C. Knudson, Washington, D. C.; Representative to the Scientific Exhibit, Dr. Ralph Worden, Los Angeles.

The Section sponsored nine exhibits in the Scientific Exhibit. There were two awards, consisting of a certificate of merit and an honorable mention.

SECTION ON PREVENTIVE MEDICINE

The Section on Preventive Medicine held three meetings, two of them joint meetings with other Sections. At the first meeting in the St. Dennis Room, Dennis Hotel, on Wednesday morning, June 10, five papers were presented. On Wednesday afternoon, the Section joined with the Section on Diseases of the Chest for two symposiums, one on pneumoconiosis and the other on heart disease and employment. On Thursday morning, June 11, the Section participated in the symposium on childbirth with six other Sections.

This was the centennial year of the Section, which was observed by an address by Dr. Walter L. Bierring, Des Moines, Iowa, on "The Changing Aspects of Preventive Medicine Over 100 Years."

At the business meeting on Wednesday, June 10, the following officers were elected: Chairman, Dr. Wilford T. Hall, Dayton, Ohio; Vice-chairman, Dr. Wilson T. Sowder, Jacksonville, Fla.; Secretary, Dr. Lemuel C. McGee, Wilmington, Del.; Delegate, Dr. Rutherford T. Johnstone, Los Angeles; Alternate Delegate, Dr. O. A. Sander, Milwaukee; Representative to the Scientific Exhibit, Dr. Paul A. Davis, Akron, Ohio.

The Section sponsored 15 exhibits in the Scientific Exhibit. Three exhibits received awards, one a certificate of merit and two an honorable mention.

SECTION ON RADIOLOGY

The Section on Radiology held four meetings, three of which were joint sessions with other Sections. On Tuesday afternoon, June 9, the Section met in Borton Hall, Dennis Hotel, for a symposium on esophageal hiatal hernia with the Sections on Diseases of the Chest and on Gastroenterology and Proctology. On Wednesday morning, June 10, there was a joint session on gastric ulcer in Trimble Hall, Claridge Hotel, with the Sections on Gastroenterology and Proctology, and on Pathology and Physiology. On Wednesday afternoon the Section met with five other Sections for the symposium and panel discussion on hepatic diseases. At the final meeting on Thursday afternoon, June 11, in the Ballroom, Shelburne Hotel, eight papers were read.

At the business meeting on Thursday, the following officers were elected: Chairman, Dr. Sydney F. Thomas, Palo Alto, Calif.; Vice-chairman, Dr. J. Paul Medelman, St. Paul, Minn.; Secretary, Dr. Traian Leucutia, Detroit; Delegate, Dr. Eugene P. Pendergrass, Philadelphia; Alternate Delegate, Dr. Wendell G. Scott, St. Louis; and Representative to the Scientific Exhibit, Dr. Richard H. Chamberlain, Philadelphia.

The Section sponsored 14 exhibits in the Scientific Exhibit. Two received awards, one a certificate of merit and one an honorable mention.

SECTION ON SURGERY, GENERAL AND ABDOMINAL

The Section on Surgery, General and Abdominal, met in Trimble Hall, Claridge Hotel, on Tuesday, Wednesday, and Thursday afternoons, June 9, 10, and 11. Fifteen papers were presented. The Section celebrated its one hundredth anniversary on Wednesday with a program devoted to the development of surgery in the United States.

At the business meeting, on Thursday, reports were heard from the Section Secretary and Delegate. A report of the representative to the American Board of Surgery was presented by the Section Secretary. A resolution was passed, asking that the name of the Section on Surgery, General and Abdominal, be changed to the Section on Surgery.

The following officers were elected: Chairman, Dr. Champ Lyons, Birmingham, Ala.; Vice-chairman, Dr. Gustaf E. Lindskog, New Haven, Conn.; Secretary, Dr. Edwin H. Ellison, Milwaukee; Delegate, Dr. Grover C. Penberthy, Detroit; Alternate Delegate, Dr. R. Russell Best, Omaha; and Representative to the Scientific Exhibit, Dr. Julian Johnson, Philadelphia.

The Section sponsored 27 exhibits in the Scientific Exhibit. Four exhibits received awards, consisting of the Hektoen Gold Medal, one certificate of merit, and two honorable mentions.

SECTION ON UROLOGY

The Section on Urology met on Wednesday, Thursday, and Friday mornings, June 10, 11, and 12 in Borton Hall, Dennis Hotel, when 17 papers were presented. In addition, there was a joint session on Wednesday afternoon with the Section on Pediatrics, at which six papers were read.

At the business meeting, on Thursday, reports were heard from the Section Secretary, Delegate, and Assistant Representative to the Scientific Exhibit. The Section deplored the fact that space for section exhibits had been curtailed and urged that the situation be corrected another year. It was voted to replenish the fund in support of the John H. Morrissey Award, and donations were received for this purpose. A motion was passed to present a certificate to each retiring chairman, the cost to come from the John H. Morrissey Fund. It was also voted to send a newsletter to members of the Section, and the Secretary was directed to investigate possibilities for this arrangement.

The following officers were elected: Chairman, Dr. Thomas A. Morrissey, New York; Vice-chairman, Dr. Harry Spence, Dallas, Texas; Secretary, Dr. Edward H. Ray, Lexington, Ky.; Asst. Secretary, Dr. Myron H. Nourse, Indianapolis; Delegate, Dr. Jay J. Crane, Los Angeles; Alternate Delegate, Dr. Earl Ewert, Boston; and Representative to the Scientific Exhibit, Dr. E. F. Poutasse, Cleveland; Assistant Representative to the Scientific Exhibit, Dr. Dean Parker, Seattle.

The Scientific Exhibit contained 13 exhibits sponsored by the Section; two exhibits received awards, one a certificate of merit and one an honorable mention. In addition, the Section presented the John H. Morrissey Award to Dr. Guy W. Leadbetter, Jr., Massachusetts General Hospital, Boston, for his exhibit on Renal Artery Replacement.

SECTION ON MISCELLANEOUS TOPICS

Three groups presented programs in the Section on Miscellaneous Topics. On Tuesday afternoon, June 9, a session on cutaneous facial disfigurements was presented under the auspices of the Committee on Cosmetics of the American Medical Association. Six papers were presented.

On Wednesday morning and afternoon, June 10, four panel discussions and one paper on the new concepts in aging were presented under the auspices of the Committee on Aging, Council on Medical Service of the American Medical Association.

On Thursday afternoon, June 11, a session on allergy was presented under the auspices of the American College of Allergists and the American Academy of Allergy.

There were 14 exhibits in the Scientific Exhibit of the Section on Miscellaneous Topics, but they were not correlated with the papers read in this Section, except in one instance. One certificate of merit was awarded.

REPORT OF THE COMMITTEE ON AWARDS FOR THE SCIENTIFIC EXHIBIT, ATLANTIC CITY, 1959

The Committee on Awards has made the following report of the awards given in the Scientific Exhibit at the 1959 Annual Meeting of the American Medical Association.

Hektoen Medal

Hektoen medals, presented to exhibits of original investigation judged on the basis of originality and excellence of presentation, were awarded as follows:

Gold Medal.—Oscar Creech, Jr., E. T. Krementz, R. F. Ryan, Keith Reemtsma, J. N. Winblad, and James L. Elliott, Tulane University School of Medicine, Charity Hospital, Touro Infirmary, and U. S. Public Health Hospital, New Orleans, for the exhibit on Treatment of Cancer by Perfusion.

Silver Medal.—James L. Tullis, L. L. Haynes, Hugh Pyle, Stanley Wallach, Robert Pennell, Mary T. Sproul, and A. Kroubesserian, Protein Foundation and U. S. Naval Hospital, Boston, for the exhibit on Clinical Use of Frozen Red Cells.

Bronze Medal.—Arild E. Hansen, Hilda F. Wiese, Arr Nell Boelsche, Mary Ellen Haggard, Doris J. D. Adam and Helen Davis, University of Texas School of Medicine, Galveston, Texas, for the exhibit on Linoleic Acid in Infant Feeding: Significance of Linoleic Acid in the Diet of Infants.

Billings Medal

Billings medals, presented to exhibits judged on the basis of excellence of correlation of facts and presentation rather than upon experimental studies, were awarded as follows:

Gold Medal.—J. Brown Farrior and Robert L. Levine, Tampa, Fla., for the exhibit on Ear Surgery in 3-D; Tympanoplasty, Stapes and Fenestration.

Silver Medal.—Arnold P. Friedman, Charles A. Carton, and Asao Hirano, Montefiore Hospital, Bronx, N. Y., for the exhibit on Facial Pain.

Bronze Medal.—Philip Schwartz, Warren State Hospital, Warren, Pa., for the exhibit on Cerebral Apoplexy: Types, Causes and Pathogenesis.

Section Awards

Certificates of Merit and Honorable Mention were awarded to the following exhibits in each section.

Section on Anesthesiology

Certificate of Merit to John Adriani and Otha Horace Yarberry, Charity Hospital and Louisiana State University School of Medicine, New Orleans, for the exhibit on Preanesthetic Medication: Old and New Concepts.

Honorable Mention to Barnett A. Greene, Samuel Berkowitz, Bernard S. Goffen, Bryce C. Anthony, Joseph R. Stein, and Joseph Katz, Adelphi Unit, Brooklyn Women's and Cumberland Hospitals, Brooklyn, N. Y., for the exhibit on Emetogenic and Antiemetic Factors and Drugs in Anesthesiology: A Simple Test Method for the Study in Man.

Section on Dermatology

Certificate of Merit to Harvey Blank, Frank J. Roth Jr., and J. Graham Smith Jr., University of Miami School of Medicine, Miami, Fla., for the exhibit on Systemic Treatment of Dermatomycoses with Griseofulvin.

Honorable Mention to Francis H. McMullan, Medical College of Virginia, Richmond, Va., for the exhibit on Basal Cell Tumors: A Classification Based on Histiogenesis.

Honorable Mention to William J. Brown, Ad Harris, W. E. Deacon, and V. H. Falcone, Communicable Disease Center, Public Health Service, Atlanta, Ga., for the exhibit on Fluorescent Treponemal Antibody Test for Syphilis.

Section on Diseases of the Chest

Certificate of Merit to Samuel H. Rosen, Armed Forces Institute of Pathology, Washington, D. C., Benjamin Castleman, Massachusetts General Hospital, Boston, and Averill A. Liebow, Yale University School of Medicine, New Haven, Conn., for the exhibit on Pulmonary Alveolar Proteinosis—A New Entity.

Honorable Mention to Richard T. Cathcart, William Fraimow, and Peter A. Theodos, Jefferson Medical College Hospital, Philadelphia, for the exhibit on Anthracosilicosis: Selected Aspects Related to the Evaluation of Disability, Cavitation, and the Unusual X-ray.

Section on Experimental Medicine and Therapeutics

Certificate of Merit to Marvin J. Seven and L. Audrey Johnson, Hahnemann Medical College, Philadelphia, for the exhibit on Metal-Binding in Medicine.

Honorable Mention to S. William Simon, Veterans Administration Center, Dayton, Ohio, for the exhibit on Tests for Oral Drug Utilization.

Honorable Mention to Edwin A. Mirand, D. T. Mount, G. E. Moore, J. T. Grace, and J. E. Sokal, Roswell Park Memorial Institute, Buffalo, for the exhibit on The Study of Viruses in Cancer.

Section on Gastroenterology and Proctology

Certificate of Merit to James L. A. Roth, A. Valdes-Dapena, George N. Stein, and H. L. Bockus, Graduate Hospital and Graduate School of Medicine of the University of Pennsylvania, Philadelphia, for the exhibit on Life History of Nonspecific Ulcerative Colitis: Relation of Anatomical Types and Clinical Course in Prognosis.

Honorable Mention to H. Mark Young, The Young Foundation for Medical Research, Los Angeles, for the exhibit on The Glomus Story.

Honorable Mention to J. Alfred Rider and Hugo C. Moeller, John O. Gibbs, Lourdes Accaoli, Jennie Lee, Beatrice Berteau, and Joyce Swader, University of California Medical Center, San Francisco, for the exhibit on Pathophysiology, Diagnosis and Treatment of Esophageal Diseases.

Section on General Practice

Certificate of Merit to Robert B. Greenblatt and Kenneth R. Baldwin, Medical College of Georgia, Augusta, Ga., for the exhibit on The Polycystic Ovary Syndrome.

Honorable Mention to J. Scott Butterworth and Edmund H. Reppert, New York University Postgraduate Medical School, New York, for the exhibit on Is Cardiac Auscultation a Lost Art?

Section on Internal Medicine

Certificate of Merit to L. G. Bartholomew, J. C. Cain, G. D. Davis, and A. H. Bulbulian, Mayo Clinic and Mayo Foundation, Rochester, Minn., for the exhibit on Misleading Calcific Shadows in the Abdomen.

Honorable Mention to Richard E. Peterson, Richard L. Lawton, and Donald V. Walz, Veterans Administration Hospital, Iowa City, for the exhibit on Uses and Abuses of Blood Transfusions.

Honorable Mention to Jan Nyboer and Alan Baker, Harper Hospital, Detroit, for the exhibit on Pulse Volume and Blood Volume Flow from Electrical Conductances: Radio-Frequency Impedance Plethysmography.

Section on Laryngology, Otology, and Rhinology

Certificate of Merit to Joel J. Pressman, Mildred B. Simon, and Walter Berman, City of Hope National Medical Center, Duarte, and University of California at Los Angeles School of Medicine, Los Angeles, for the exhibit on Primary Repair of Defects Following Removal of Tumors of the Face.

Honorable Mention to Chevalier L. Jackson, John V. Blady, Charles M. Norris, Robert Robbins, and Ernest L. McKenna, Temple University Medical Center, Philadelphia, for the exhibit on Cancer of the Larynx and Hypopharynx: A Study of the Application of Classification and Staging.

Section on Military Medicine

Certificate of Merit to Otis O. Benson, Paul Campbell, and Irving B. Davis, School of Aviation Medicine, U. S. Air Force, Randolph Air Force Base, Texas, for the exhibit on Space Medicine Research.

Honorable Mention to Richard L. Bernstine and James H. Nelson Jr., U. S. Naval Hospital, St. Albans, N. Y., for the exhibit on Retrograde Femoral Arteriography in Obstetrics and Gynecology.

Section on Nervous and Mental Diseases

Certificate of Merit to Paul M. Ellwood Jr., Elizabeth Kenny Institute and University of Minnesota Medical School, Minneapolis, for the exhibit on Neurological Examination of Infants.

Section on Obstetrics and Gynecology

Certificate of Merit to Harold A. Kaminetzky, E. McGrew, R. Phillips, O. Saphir, M. Leventhal, and T. Kline, University of Illinois College of Medicine and Michael Reese Hospital, Chicago, for the exhibit on Cervical Epithelial Dysplasia—Experimentally Produced.

Honorable Mention to Michael J. Jordan, Genevieve M. Bader, and Emerson Day, Memorial Center for Cancer and Allied Diseases, New York, for the exhibit on Management of Atypical Lesions of the Cervix.

Section on Ophthalmology

Certificate of Merit to Gilbert Baum and Ivan Greenwood, Veterans Administration Hospital, Bronx, N. Y., and National Institutes of Health, Washington, D. C., for the exhibit on Application of Ultrasonic Locating Techniques to Ophthalmology.

Honorable Mention to Theodor Wanko, National Institutes of Health, Bethesda, Md., for the exhibit on The Crystalline Lens.

Honorable Mention to Mansour F. Armaly, State University of Iowa College of Medicine, Iowa City, for the exhibit on Intraocular Effects of the Parasympathetics in the Cat: Morphology and Fluid Dynamics.

Section on Orthopedic Surgery

Certificate of Merit to James A. Nicholas, Philip D. Wilson, and Robert H. Freiberger, Hospital for Special Surgery, The New York Hospital-Cornell Medical Center, New York, for the exhibit on A Clinical Study of Demineralizing Bone Disease.

Honorable Mention to J. I. Kendrick, George S. Phalen, and L. J. McCormack, Cleveland Clinic, Cleveland, for the exhibit on Benign Soft Tissue Tumors of the Hand.

Section on Pathology and Physiology

Certificate of Merit to Hans Elias and John E. Pauly, Chicago Medical School, Chicago, for the exhibit on The Adrenal Cortex in Health and Disease.

Honorable Mention to Erving F. Geever, Harold L. Upjohn, and Stanley M. Levenson, Walter Reed Army Institute of Research, Washington, D. C., for the exhibit on The Microscopic Pathology of Collagen Inhibition in Experimental Scurvy.

Section on Pediatrics

Certificate of Merit to Theodore H. Ingalls and Francis J. Curley, University of Pennsylvania School of Medicine, Philadelphia, for the exhibit on Congenital Anomalies: Experimental Production of Cranioschisis.

Honorable Mention to Anthony A. Albanese, Reginald A. Higgons, and Louise A. Orto, St. Luke's Hospital, New York, and St. Luke's Convalescent Hospital, Greenwich, Conn., for the exhibit on Amino Proteins and Their Utilization by Young Children.

Section on Physical Medicine

Certificate of Merit to Earl F. Hoerner, Joseph B. Rogoff, and Jerome S. Tobis, New York Medical College, New York, for the exhibit on Pain Weakness: Electrodiagnostic Evaluation.

Honorable Mention to Charles D. Bonner, Holy Ghost Hospital Rehabilitation Unit, Cambridge, Mass., for the exhibit on Muscle Rehabilitation by Local Steroid Therapy and Sling Suspension.

Section on Preventive Medicine

Certificate of Merit to John C. Pruitt, Albert W. Hilberg, Raymond F. Kaiser, Richard A. Malmgren, and John F. Potter, National Cancer Institute, Bethesda, Md., for the exhibit on Studies of Cancer Cells in Circulatory Blood.

Honorable Mention to Peter Hamill, U. S. Public Health Service, Washington, D. C., for the exhibit on Air Pollution Is a Nationwide Problem.

Honorable Mention to Howard A. Buechner, Jordan Thompson, and Oscar Blitz, Veterans Administration Hospital, New Orleans, for the exhibit on Bagassosis: A Medical Enigma.

Section on Radiology

Certificate of Merit to Robert S. Sherman and Daniel Wilner, Memorial Center for Cancer and Allied Diseases, New York, for the exhibit on Roentgen Problems in Paget's Disease.

Honorable Mention to Emanuel Salzman, R. P. Spurck, L. C. Kier and D. H. Watkins, Denver General Hospital and the University of Colorado School of Medicine, Denver, for the exhibit on Opacifying Gallstones.

Section on Surgery, General and Abdominal

Certificate of Merit to E. Stanley Crawford, Michael E. De Bakey, William S. Fields, Denton A. Cooley and George C. Morris Jr., Baylor University College of Medicine, Houston, Texas, for the exhibit on Surgical Considerations in Treatment of Cerebral Arterial Insufficiency.

Honorable Mention to James S. Clarke, Paul K. McKissock, Ira Miller, and Kenneth Cruze, Veterans Administration Center, Los Angeles, for the exhibit on Peptic Ulcer in Cirrhosis and After Portacaval Shunt.

Honorable Mention to O. H. Beahrs, K. D. Devine, and L. B. Woolner, Mayo Clinic and Mayo Foundation, Rochester, Minn., for the exhibit on Tumors of the Parotid Gland: Their Surgical Management.

Section on Urology

Certificate of Merit to Hans H. Zinsser and Clifford Wahlberg, Columbia University College of Physicians and Surgeons, New York, for the exhibit on Urease Inhibitors in Urological Infections: Stone Prevention and Resistance Changes.

Honorable Mention to John W. Draper, Michael Sierp, Paul Braunstein, and William Samellas, Bellevue Hospital and Cornell University Medical College, New York, for the exhibit on The Stimulation of Callus Formation in Fractures by Interposed Urothelium.

Section on Miscellaneous Topics

Certificate of Merit to Henry D. Ogden, New Orleans, and Marvin Fuchs, Washington, D. C., for the exhibit on Basic Fundamentals in the Treatment of Asthma.

Exhibit Symposium on Arthritis and Rheumatism

Certificate of Merit to John H. Talbott and Donald M. Wilson, University of Buffalo School of Medicine and Buffalo General Hospital, Buffalo, for the exhibit on Gout and Blood Dyscrasias.

Exhibit Symposium on Diabetes

Certificate of Merit to Howard F. Root, Elliott P. Joslin, Alexander Marble, Priscilla White, Allen P. Joslin, Robert F. Bradley, and Leo P. Krall, Joslin Clinic, Boston, for the exhibit on Diabetes Mellitus Today.

Medical Photography

A Certificate of Merit is awarded to William Atkinson, University of Miami School of Medicine, for his work on medical photography in the exhibit on Systemic Treatment of Dermatomycoses with Griseofulvin.

Honorable Mention is given to Thomas J. Lannon, Cleveland Clinic, Cleveland, for his work on medical photography in the exhibit on Serotonin Sensitivity in Rheumatoid Arthritis and Related Diseases.

Medical Illustration

A Certificate of Merit is awarded to Leonard D. Dank, New York, for his work on medical illustration in the exhibit on The Red Eye, Diagnosis and Treatment.

Honorable Mention is given to Will Symmes and Ralph Sweet, San Francisco, for their work on medical illustration in the exhibit on Pathophysiology, Diagnosis and Treatment of Esophageal Diseases.

Certificates of Appreciation

Certificate of Appreciation to Gordon M. Wyant and Allen B. Dobkin, University of Saskatchewan College of Medicine, Saskatoon, Sask., Canada, for the exhibit on Physiologic Effects of Intravenous Anesthesia.

Certificate of Appreciation to Andrew Muir, Lanark, Scotland, for his exhibit on Aspirin and the Stomach.

Comments

The Committee on Awards wishes to thank all of the scientific exhibitors for their contribution to graduate medical education and the Section Representatives for their assistance.

The members of the Committee on Awards included Drs. Frank P. Foster, Boston, Chairman; Lester R. Dragstedt, Chicago; Rubin H. Flocks, Iowa City; Everett C. Fox, Dallas, Texas, and Sam H. Sanders, Memphis, Tenn.

MEDICAL NEWS

ARIZONA

General Practice Meeting in Scottsdale.—The American Academy of General Practice, Arizona Chapter, will meet Oct. 15-17 at the Hotel Valley Ho, Scottsdale. A panel discussion, "Cutaneous Medicine," will be conducted the morning of Oct. 17, with Dr. William E. Ragsdale Jr., Phoenix, presenting, "Malignancy of the Skin," and Dr. Walter W. Wilson, Coeur D'Alene, Idaho, giving, "Griseofulvin, a New Oral Treatment for Ringworm." Twelve other papers are scheduled, including "Caution, Curves Ahead," by Mr. Mac F. Cahal, executive director of the academy. Exhibits are planned. For information, write Dr. Arthur V. Dudley Jr., 1524 N. Norton, Tucson, Ariz., Convention Chairman.

CALIFORNIA

General Practice Meeting in Los Angeles.—The California Academy of General Practice will meet Oct. 11-14, at the Hotel Statler, Los Angeles. Over 20 papers are scheduled, including the following special lectures:

Clinical Use and Technique of Hypnosis, Dr. Milton H. Erickson, Phoenix, Ariz. (Stanley R. Truman Lecture).
Diagnosis and Treatment of Hypertension, Dr. James B. Donaldson, Philadelphia (Hodges Memorial Lecture).
The Use of Steroids in Arthritis, Dr. Philip S. Hench, Rochester, Minn. (Ivan C. Heron Lecture).

A panel discussion, "Modern Treatment of Carcinoma of the Breast," will be moderated by Dr. Forrest M. Willett, San Francisco. Technical exhibits are planned.

COLORADO

Dr. Newman Comes to Denver.—Dr. Melvin M. Newman resigned as associate professor of surgery at the State University of New York Downstate Medical Center, Brooklyn, Sept. 30 to accept the post of director of surgery at the National Jewish Hospital, Denver. Dr. Newman came to the downstate center's department of surgery in July, 1954, as assistant professor. He has been in charge of the university's thoracic surgery service at the Kings County Hospital for several years.

Personal.—Dr. Juan A. del Regato, director of the Penrose Cancer Hospital, Colorado Springs, has been elected president of the section on radiotherapy of the Pan American Medical Association, which will hold its 35th anniversary congress in Mexico City, May 2-11, 1960.——Dr. Robert J. Glaser, dean and professor of medicine, University of Colorado School of Medicine, Denver, was recently named vice-president for medical affairs at the university. He will continue to serve as dean of the School of Medicine.

DISTRICT OF COLUMBIA

Personal.—Dr. Vane M. Hoge was appointed assistant director of the Washington Service Bureau of the American Hospital Association. Dr. Hoge resigned as executive director of the Hospital Planning Council for Metropolitan Chicago to accept the AHA appointment, which was effective July 1.——In June, Dr. Lawrence S. Lilienfield, assistant professor of medicine, Georgetown University School of Medicine, was made a fellow of the American Association for the Advancement of Science, was elected president of the D. C. Chapter of the American Federation for Clinical Research, and was appointed councillor of the eastern section of the federation.——The speaker for the annual Lewis Harvey Taylor Lecture of the American Therapeutic Society was Dr. Edward P. Freis, associate professor of medicine, Georgetown University School of Medicine, who spoke before the society June 7, at Atlantic City.

ILLINOIS

Dr. Camp Honored.—The Warren County Medical Society and the Monmouth Medical Club on Sept. 24 honored Dr. Harold M. Camp, of Monmouth, secretary-treasurer of the Illinois State Medical Society. The occasion marked Dr. Camp's 50 years as a physician. A dinner was held in Grier Hall of Monmouth College and a program was arranged by Dr. Charles P. Blair, of Monmouth, president of the Warren County Medical Society. Dr. Camp, following his graduation from Northwestern University Medical School in 1909, entered practice in Monmouth. In 1924 he was elected secretary of the state society.

Chicago

Dr. Adams Named Surgery Chairman.—Dr. William E. Adams, Raymond Professor of Surgery at the University of Chicago, was appointed chairman of the department of surgery at that institution, effective Aug. 1. Dr. Adams is president of the American Association for Thoracic Surgery and a councilor of the Illinois State Medical Society.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Orthopedic Meeting in Chicago.—The Chicago Orthopaedic Society will meet Oct. 9 at the Palmer House, with Dr. Charles F. Woodhouse, Chicago, presenting "Arterial Transplant into Bone." Dr. Carlo S. Scuderi, Chicago, will give "Present Status of Orthopaedic Surgery in Italy." All physicians are invited. For information, write Dr. Jerome G. Finder, 111 N. Wabash Ave., Chicago 2, Secretary.

Medical History Meeting.—There will be a meeting of the Society of Medical History of Chicago at the Institute of Medicine (fourth floor, 86 E. Randolph St.) on Wednesday, Oct. 14, 8 p. m. This is an open meeting. Dr. George V. LeRoy, associate dean of the biological sciences, University of Chicago, will present, "On the Asthma." Ilza Veith, Ph.D., associate professor, department of the history of medicine, University of Chicago, and president of the society, will present, "A Medical Historian in Japan."

Dr. Spaeth to Speak at Annual Luncheon.—The annual luncheon of Michael Reese Hospital Eye Alumni Oct. 13 at the Stanford Club in Chicago, will highlight the achievements of the late Dr. Henry S. Gradle, who headed the department of ophthalmology at the medical center from 1925 to 1950. Guest speaker is Dr. Edmund B. Spaeth, of Philadelphia, who will review Dr. Gradle's contributions to eye research and surgery as well as to international medical relations, notably in the founding of the Pan-American Academy of Ophthalmology in 1940. The luncheon is a yearly event held in connection with the American Academy of Ophthalmology and Otolaryngology, which meets this year Oct. 12-17 in Chicago. It is open to all interested Reese interns as well as former eye residents and nurses associated with the hospital or with Dr. Gradle.

INDIANA

State Convention in Indianapolis.—The 110th convention of the Indiana State Medical Association will be held Oct. 6-9 at the Murat Temple, Indianapolis. Dr. Kenneth L. Olson, South Bend, president of the association will open the first general meeting. Papers to be presented by out-of-state speakers are as follows:

Cancer of the Breast, Dr. George Crile Jr., Cleveland.
Hypophysectomy in the Treatment of Advanced Cancer of the Breast, Dr. Bronson S. Ray, New York.
Problem of Ovarian Cysts, Dr. J. Donald Woodruff, Baltimore.
Hyperfunctioning Lesions of the Adrenal Glands, Dr. James T. Priestly, Rochester, Minn.
Pituitary Tumors, Dr. Ray.
Surgical Anatomy of the Colon and Rectum, Dr. C. Naunton Morgan, London, England.
Ulcerative Colitis, Dr. Charles W. Mayo, Rochester, Minn.
The Tired Mother Syndrome, Dr. Leonard L. Lovshin, Cleveland.
Convalescence Following Illness and Surgery, Dr. N. Henry Moss, Philadelphia.
General Considerations in the Use of Steroids, Dr. Robert M. Salassa, Rochester, Minn.
Carcinoma of the Lower Colon and Upper Rectum, Dr. Mayo.
The Treatment and Care of Imperforate Anus, Dr. Arthur DeBoer, Chicago.

The speaker at the annual dinner Oct. 7, 7 p. m. will be Carl Winters, Ph.D., public relations department, General Motors Corporation, Detroit. The program is approved for category II credit by the Indiana Academy of General Practice, and instruction courses are approved for category I. A trap-skeet shoot and a golf tournament are planned. For information write Mr. James A. Waggener, 1021 Hume Mansur Building, Indianapolis 4, Executive Secretary.

LOUISIANA

Symposium on Lipid Metabolism.—The Tulane University School of Medicine and the National Vitamin Foundation will present a Symposium on the Role of Vitamins and Other Nutrients in Lipid Metabolism, to be held on the Tulane Campus, New Orleans, Oct. 16. Factors thought to be involved in the production or possible prevention of atherosclerosis will be covered, among them fatty acids, cholesterol, vitamin B_6, nicontinic acid, and vitamin E. Information regarding the symposium may be obtained from Dr. Grace A. Goldsmith, Tulane University of Louisiana School of Medicine, New Orleans, or The National Vitamin Foundation, Inc., 149 E. 78th St., New York 21.

General Practice Meeting.—The Louisiana Academy of General Practice will hold its 13th annual scientific assembly on Oct. 20-22 at the Capitol House in Baton Rouge, Dr. Francis I. Nicolle, of New Orleans, secretary of the organization, announced. The Congress of Delegates of the academy will be in session on the morning of Oct. 20. Speaker of the congress is Dr. Eldredge L. Carroll, of Columbia, and vice-speaker is Dr. John G. McClure, of Welsh. The scientific sessions will begin on the afternoon of Oct. 20. Dr. Esmond A. Fatter, New Orleans, will preside at the opening session. The Wednesday morning session will have Dr. Joseph W. Crookshank, of Lake Charles, president-elect, as its presiding officer and on Wednesday afternoon Dr. Julius W. Daigle, of Paincourtville, immediate past-president, will be in charge of the session. The scientific portion of the program has been accepted for 11 hours of category I credit by the American Academy of General Practice. Speakers will include Dr. Nicholas J. Chetta, New Orleans; Dr. Carl A. Nau Jr., Galveston, Texas; Dr. Vincent P. Collins, Houston; Dr. Joseph A. Sabatier Jr., Baton Rouge; Dr. Robert I. Wise, Philadelphia; Dr. Philip Thorek, Chicago; Dr. Irving Redler, New Orleans. Dr. David L. Markstein, investment counsellor and seminar lecturer at Loyola University in New Orleans, will present "Dangers and Profits in Investing in the World of Tomorrow." Two medical films will complete the scientific program. On Wednesday, Oct. 21, the Louisiana academy will hold its annual installation dinner. Sixty pharmaceutical and allied companies will present technical exhibits during the meeting.

MARYLAND

Symposium on Prenatal Nutrition.—The role of maternal nutrition in the production of congenital malformations and reproductive failure will be stressed at a symposium scheduled for Oct. 16-17 at the Johns Hopkins Hospital in Baltimore. The Symposium on Prenatal Nutrition will cover such topics as protein nutrition in pregnancy, metabolism of iron, vitamin B_{12} and folic acid in pregnancy, and genetics and vitamin B_{12} deficiency. For information write Bacon F. Chow, Ph.D., Associate Professor, Department of Biochemistry, the Johns Hopkins University School of Hygiene and Public Health, Baltimore, or Dr. Nicholson J. Eastman, Professor of Obstetrics and Gynecology, the Johns Hopkins University School of Medicine, Baltimore.

MASSACHUSETTS

Symposium on Disability and Comprehensive Medicine.—The Liberty Mutual Insurance Company will sponsor a symposium, "The Growing Challenge of Disability Control in an Era of Comprehensive Medical Care," Oct. 15-16 at the John Hancock Hall and Hotel Sheraton-Plaza, Boston. Panel discussions and moderators are planned as follows: "Cardiac Disability," Dr. Paul Dudley White, Boston; "Psychological Complications in Disability," Dr. Carl A. L. Binger, Cambridge; and "Connective Tissues and the Degenerative Diseases of Aging," Francis O. Schmitt, Ph.D., Massachusetts Institute of Technology. The program includes the following papers:

Industrial Management's Role in the Control of Disability, Mr. Edward J. Sullivan, Turner Construction Co.
The Role of Insurance in the Control of Disability, Mr. S. Bruce Black, Liberty Mutual Insurance Co.
The Socio-Economic Responsibilities of Medicine, Dr. Gunnar A. Gundersen, La Crosse, Wis., Past-President, American Medical Association.
The Economic Challenges in Disability Control, Mr. George Bugbee, president, Health Information Foundation.
Labor's Role in the More Effective Control of Disability, Mr. Jerome Pollack, Detroit.
The Role of the Bar and the Judiciary in Controlling Disability, Mr. David W. Peck, New York City.
Government's Role in the Control of Disability, Miss Bertha S. Adkins, Washington, D. C.

MICHIGAN

Center for Medical Research.—Dow Corning Corporation announced the founding of the Dow Corning Center for Aid to Medical Research Aug. 14. In making the announcement, Mr. R. W. Collings, president, said, "the purpose of the center will be to aid medical research by supplying technical assistance by acting as a clearing-house for information about the use of silicones in medicine and surgery, and by cooperating in research in organosilicon chemistry in relation to the human body." Offices of the new center will be at Midland. The director will be Rob Roy McGregor, Ph.D., and the executive secretary Mr. Silas A. Braley. Dr. McGregor has been a member of the research team of Dow Corning since its founding in 1943. The new facility will serve as a communication center, Dr. McGregor said, "to answer inquiries about the medical uses of silicones, to collaborate on solving technical problems, and to report on work in progress. There will be no charge for this service."

Annual Meeting on Blood Banks.—The 5th annual meeting of the Michigan Association of Blood Banks will be held Oct. 10 at the David Whitney House, headquarters of the Wayne County Medical Society, Detroit. Dr. Ralph M. Hartwell, New Orleans, president, American Association of Blood Banks, will moderate the morning session at which Dr. Elmer R. Jennings, president of the Michigan association, will present an address. The program includes the following papers:

Medicolegal Aspects of Operating a Blood Bank, Frederick J. Buesser Jr., LL.B., Detroit.
Drug Dependent Positive Coombs Test, Dr. Ernest E. Muirhead, Detroit.
Quantitative Aspects of Anti-Rh Inhibition, Emanuel Hackel, Ph.D., East Lansing.
Blood Bank Problems Relating to Open Heart Surgical Procedures, Dr. William J. Kuhns, Pittsburgh.
Studies on Survival of Platelets and Erythrocytes, Dr. Max M. Strumia and Dr. Paul V. Strumia, Bryn Mawr, Pa.
Screening of Hemorrhagic Disorders for the Small Laboratory, Lee A. Hyndman, Ph.D., Lansing.
Use of Fluorescent Antibodies in the Detection of Minor Erythrocyte Populations, Dr. Flossie Cohen, Dr. Wolf W. Zuelzer, and Margaret Evans, M.S., Detroit.

A round-table luncheon is planned. For information, write Dr. Frank R. Ellis, Chairman, Program Committee, 1010 Antietam St., Detroit 7.

MINNESOTA

Personal.—Dr. Frank H. Krusen, Rochester, who founded the Section of Physical Medicine and Rehabilitation of the Mayo Clinic in 1935, was appointed special assistant for health and medical affairs to the director of the Office of Vocational Rehabilitation of the Department of Health, Education, and Welfare. Dr. Krusen will assume the new post about Sept. 15.——Dr. S. Marx White, of Minneapolis, was awarded Northwestern University Alumni Association's merit award "in recognition of worthy achievement which has reflected credit upon Northwestern University." Dr. White, one of the founders of the Nicollet Clinic, received his medical degree from Northwestern in 1897.

MONTANA

Society News.—The Montana Chapter of the American Academy of General Practice installed Dr. Harry R. Soltero, Billings, as president to succeed Dr. Amos R. Little Jr., Helena, Dr. Philip D. Pallister, Boulder, was named president-elect and Dr. Paul J. Seifert, Libby, vice-president. Dr. Vernon D. Standish, Big Timber, was reelected secretary-treasurer.——At the annual conference of the Montana Rehabilitation Association in Billings, during June, Dr. James A. Shown, Great Falls, was named president-elect, succeeding Mr. John J. Earls, Helena, was installed as president for the forthcoming year. Dr. Jess T. Schwidde, Billings, is immediate past-president of the association.

NEW JERSEY

Symposium on Lipids and Diabetes.—The New Jersey Diabetes Association in cooperation with the New Jersey State Department of Health will present its seventh annual Symposium on Lipids and Diabetes in Newark Oct. 21. Four papers are scheduled as follows:

Fat: Its Relationship to the Treatment of Diabetes, Dr. Leo P. Krall, Boston.
Some Aspects of Lipid Metabolism in Relation to Atherosclerosis, Dr. Herbert J. Kayden, New York City.
Effects of Fatty Infiltration of the Liver upon Sensitivity to Insulin Action, Michael Somogyi, Ph.D., St. Louis.
Fat: Liver and Diabetes, Dr. Carroll M. Leevy, Jersey City.

A panel discussion, "Lipids and Diabetes," will be moderated by Dr. Garfield G. Duncan, Philadelphia. President of the New Jersey Diabetes Association is Dr. William Levison. Members of the American Academy of General Practice will receive three hours credit under category II for attendance.

NEW YORK

Center for Arthritis Evaluation.—Two March of Dimes research grants totaling $145,080 have been awarded to the University of Rochester School of Medicine and Dentistry to establish a model arthritis evaluation and demonstration center, and to study blood factors as a clue to rheumatoid arthritis. The two research projects will be directed by Dr. Ralph F. Jacox, associate professor of medicine, who will conduct the arthritis evaluation and demonstration center, and Dr. John H. Vaughan, associate professor of medicine, who will direct the study of blood factors. The arthritis center in Rochester will be located in the University of Rochester Medical Center with its two affiliated teaching hospitals, the Strong Memorial Hospital and Rochester Municipal Hospital. It will have complete resources for diagnostic, orthopedic, pediatric, psychiatric, and social service care of patients with arthritis. The center will have triple functions of care, education, and research as related to rheumatic diseases. The new center will offer outpatient treatment primarily. However, hospital beds will be available for in-patient treatment when necessary. The program under the university grant will be administered by the department of medicine.

Personal.—The retirement of Dr. Morton L. Levin, Albany, as assistant commissioner for medical services was announced. Dr. Levin, associated with the New York State Health Department since 1936, is a former president of the Public Health Cancer Association and the New York State Epidemiological Society.——Appointment of Dr. Loftus L. Bryan, Marcy, as assistant commissioner in the State Department of Mental Hygiene was announced. He has been acting commissioner since Dec. 4, 1958. Dr. Bryan will be in charge of the division of in-patient services, having responsibility for the administration of occupational therapy, nursing, recreational and safety services, and for medical inspection of all state and licensed mental institutions.——Dr. Thomas L. Hawkins Jr., of the Albany Medical College faculty, was awarded a special fellowship by the Nathan Hofheimer Foundation, New York, to undergo advanced training in hematology. Dr. Hawkins has gone to Salt Lake County General Hospital and the University of Utah College of Medicine, Salt Lake City, where he will spend 10 months studying clinical and experimental hematology under Dr. Maxwell M. Wintrobe and Dr. George E. Cartwright.

New York City

Director Named for Radioactivity Laboratory.—Mr. Merril Eisenbud was appointed professor of industrial medicine at New York University Post-Graduate School of Medicine and will assume direction of a new laboratory concerned with the study of long-range effects of radioactivity on man to be established at the Medical Center. The laboratory will be a unit of the Institute of Industrial Medicine, of which Norton Nelson, Ph.D., is director. Organization of the radiation study was made possible by a 10-year grant from the Rockefeller Foundation. The objective of the project will be the evaluation and prevention of radiation hazards for the general population as well as in industry. Professor Eisenbud has been associated with the atomic energy program since he joined the Atomic Energy Commission's Health and Safety Laboratory in 1947.

Society News.—The following officers of the Kings County Radiological Society were elected for 1959-1960: president, Dr. Ernest I. Melton; vice-president, Dr. Aaron R. Tolk; and secretary-treasurer, Dr. C. Philip Naidorf, 411 Parkside Ave., Brooklyn 26.——At the May meeting of the Brooklyn Ophthalmological Society the following members were elected to office: Dr. Ira W. Mensher, president; Dr. Edward Saskin, vice-president; Dr. Nicholas P. Tantillo, secretary-treasurer; and Dr. Angelo B. Rizzuti, associate secretary-treasurer.

NORTH CAROLINA

Annual Symposium in Raleigh.—The 11th medical symposium of the Raleigh Academy of Medicine will be held at the Carolina Hotel in Raleigh Oct. 22, under the subject, "Headache." Dr. Frank P. Powers, president of the academy, will preside. Speakers for the symposium will include Dr. Arnold P. Friedman, New York City; Dr. Lawrence C. Kolb, New York City; Dr. H. Houston Merritt, New York City; and Dr. John R. Graham, Boston. Interested physicians are invited. For information, write Dr. Walter H. Wilson, Professional Building, Raleigh, N. C.

OREGON

Northwestern Pathologists Meeting.—The fall meeting of the Pacific Northwest Society of Pathologists will be held Oct. 15-17 in Gearhart. Dr. Lauren V. Ackerman, professor of surgical pathology and pathology, Washington University School of Medicine, St. Louis, will present, "Pseudosarcoma of Soft Tissue." A slide seminar is planned for the morning of Oct. 17. The seminar and scientific program are open to all interested physicians. For information, write Dr. Nelson R. Niles, University of Oregon Medical School, Portland 1, Ore., Secretary.

PENNSYLVANIA

Society News.—Officers of the Pennsylvania Radiological Society elected for 1959-1960 are as follows: Drs. D. Alan Sampson, Ardmore, president; Carl B. Lechner, Erie, president-elect; Thomas J. Conahan, Hazleton, first vice-president; Thomas A. Campbell, York, second vice-president; Walter P. Bitner, Harrisburg, secretary-treasurer: John H. Harris Jr., Philadelphia, editor; Marlyn W. Miller, Altoona, associate editor, John H. Harris, Harrisburg, councilor to American College of Radiology; and Newton Hornick, Pittsburgh, alternate councilor. The next annual meeting will be held at Pocono Manor on May 14-15, 1960.

PUERTO RICO

Meeting of Physicians in Santurce.—The American College of Physicians ninth regional meeting will be held at the Puerto Rico Medical Association Building, Santurce, Oct. 9-10. The program will open with a symposium, "Medical Aspects of Schistosomiasis Mansoni," presented in collaboration with the Puerto Rican Committee for Bilharzia Control, and will include "Medical Treatment of Schistosomiasis Mansoni," by Dr. F. Hernandez-Morales, governor of the college for Puerto Rico. Dr. Chester S. Keefer, Boston, president-elect of the college, will present, "From Chronic Bronchitis to Cor Pulmonale," the evening of Oct. 9 and will be luncheon speaker Oct. 10. The program includes a total of 22 papers. For information, write The American College of Physicians, 4200 Broad St., Philadelphia 4.

TEXAS

Dr. McGanity Named Department Chairman.—Dr. William J. McGanity was appointed professor and chairman of the department of obstetrics and gynecology of the University of Texas Medical Branch School of Medicine at Galveston, effective Jan. 1, 1960. He has been visiting professor of obstetrics and gynecology since Sept. 1, 1959. He succeeded Dr. Garth L. Jarvis, who will continue as professor in the department. Dr. McGanity comes to the University of Texas from Vanderbilt University School of Medicine, Nashville, Tenn., where he served as an associate professor.

WEST VIRGINIA

Hospital Seminars.—A series of monthly seminars including lectures on nontechnical health subjects to which the public is invited has been arranged by the Memorial General Hospital in Elkins for the fall and winter of 1959-1960. The first meeting, devoted to a discussion of cancer, sponsored by the Tumor Clinic, was held in the library conference room of the hospital, Sept. 8. Dates for the following monthly meetings will be decided upon by the committee: October, "Is Your Child Healthy?," department of pediatrics; November, "Use and Abuse of Radiation," department of radiology; December, "The Advance of Pathology in Relation to Disease," department of pathology; January, "Facts and Fallacies in Female Disease," department of gynecology and obstetrics; February, "Heart Attack," department of cardiology; March, "Anesthesia and the Patient," department of anesthesiology; April "Abdominal Pain," department of surgery; May "Glaucoma," department of ophthalmology; and June, "100 Years of Dental Progress," department of dentistry.

Personal.—Dr. William P. Bittinger, of Summerlee and Dr. Doff D. Daniel, of Beckley, were reappointed by Governor Cecil H. Underwood as members of the West Virginia Medical Licensing Board for a five-year term, beginning July 1. Drs. Bittinger and Daniel have been members of the board since 1949. The Governor also reappointed Dr. Hu C Myers, of Philippi, as a member of the advisory board to the State Board of Health on Hospital Licensing, a post he has held since 1949. The appointment, effective July 1, is for a term of seven years.—Dr. Charles M. Scott, of Bluefield, was elected president of the West Virginia Chapter of the Medical College of Virginia Alumni Association. He succeeds Dr. Marion F. Jarrett, of Charleston.

WISCONSIN

Personal.—Dr. Alfred S. Evans, who for the past six years has been director of the preventive medicine section of student health and associate professor of medical microbiology, University of Wisconsin Medical Center, Madison, was appointed chairman of its newly established department of preventive medicine and director of the State Laboratory of Hygiene. Dr. Evans will replace retiring Dr. William D. Stovall as Director of the State Laboratory of Hygiene.——Dr. Max J. Fox, a member of the faculty of Marquette University School of Medicine, Milwaukee, since his graduation from its medical school in 1922, was named "Marquette Alumnus of the Year" at a dinner for past-presidents of the alumni association on May 14. He received a citation at Marquette's commencement exercises June 7.

GENERAL

Mid-West Allergy Forum.—The Mid-West Forum on Allergy will hold its third annual meeting Oct. 31-Nov. 1 at the Sheraton-Blackstone Hotel, Chicago. This meeting of the forum is sponsored by the Chicago Society of Allergy. For information, write to Dr. Leon Unger, 185 N. Wabash Ave., Chicago 2.

Music Therapy Convention.—The 10th annual national music therapy convention, sponsored by the National Association for Music Therapy, Inc., the department of music and the continuing education service of Michigan State University, will be held at the Kellogg Center for Continuing Education at Lansing, Mich., Oct. 9-11. The program includes Dr. Henry R. Rollin and Mrs. Maier Brooking, both of London, England. Exhibits and displays are planned. Registration fee is $6. For information, write the Kellogg Center for Continuing Education, Michigan State University, East Lansing, Mich.

Plastic Surgery Meeting in Chicago.—The fall meeting of the American Society of Facial Plastic Surgery will be held Oct. 15-17 at the Palmer House, Chicago. On Oct. 15 the meeting will be open to the medical profession, and the program will be a Colloquy on Refinements in Facial Plastic Surgery and will include a panel discussion. On Oct. 16 operative demonstrations, lectures, and discussions on rhinoplasty and otoplasty are planned. Operative clinics will be held Oct. 17, at which forehead flaps, bone and cartilage grafts, and skin grafts will be considered. For information, write Dr. Samuel M. Bloom, Secretary, 123 E. 83rd St., New York 23.

Medical History Essay Medal.—The American Association for the History of Medicine has established a medal to be granted annually to "the author of the best essay submitted to the association." The medal has been named in honor of William Osler, "who more than any other teacher of medicine succeeded in creating among students enthusiasm for the history of medicine." Students of medicine are invited to compete for the Osler Medal. Essays submitted should not exceed 10,000 words in length on a historical medical subject of the student's own choice. Deadline for this year will be April 1, 1960. Essays should be submitted by that date to Dr. Samuel X. Radbill, 7043 Elmwood Ave., Philadelphia 42.

Otorhinologic Surgery Meeting in Chicago.—The American Otorhinologic Society for Plastic Surgery, Inc., will meet Oct. 11 at the Conrad Hilton Hotel, Chicago, under the presidency of Dr. Raymond S. Rosedale, Canton, Ohio. Dr. Bagher Sotoodeh, San Antonio, Texas, will present, "Surgery of Laryngeal Webs," and Dr. Gonzalo Obregon, Iowa City, will give, "Thyro-Glossal and Branchial Cysts." Evening panel discussions moderated by Dr. John T. Dickinson, Pittsburgh, will be held under the following titles: Neck Surgery, Miscellaneous Topics on Plastic Surgery of the Head, and A Method of Rhinoplasty. For information, write Dr. Joseph G. Gilbert, Secretary, 75 Barberry Lane, Roslyn Heights, N. Y.

Meeting of Life Insurance Medical Directors.—The 68th annual meeting of the Association of Life Insurance Directors of America will be held Oct. 21-23 at the Hotel Statler Hilton, New York City, under the presidency of Dr. Henry B. Kirkland. Dr. Louis M. Orr, President, American Medical Association, will present, "Uncle Sam with a Stethoscope," the morning of Oct. 21. Other papers include the following:

Accomplishments and Needs of Cardiovascular Research, Dr. Francis R. Dieuaide, New York City.
The Neurotic Claimant: Evaluation of Disability, Dr. Peter G. Denker, New York City.
Highlights of the New Build and Blood Pressure Study, Dr. John J. Hutchinson, New York City.
Which Erring Men Call Chance, Dr. Frank B. Berry, Washington, D. C.
The Master "2-step" Electrocardiographic Test Brought up to Date, Dr. Arthur M. Master, New York City.
Factors in the Evolution of Occlusive Coronary Artery Disease, Dr. Milton Helpern, New York City.
Advances in Surgery: Their Effects on Medical Underwriting, Dr. Claude M. Lee Jr., Cincinnati.

At the banquet, 6:30 p. m., Oct. 22, Mr. Robert H. Trench Thompson, United States Manager, British Overseas Airways Corporation, New York City, will present, "Civil Aviation and World Politics." The program will conclude with a symposium, "Our Public Relations and the Work and Aims of the Health Insurance Council." For information, write Dr. Royal S. Schaaf, P. O. Box 594, Newark 1, N. J., Secretary.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

Area	Sept. 5, 1959		Sept. 6 1958 Total

Catastrophes Decrease.—Catastrophes—accidents in which five or more persons are killed—took more than 750 lives in the United States during the first six months of this year, it is reported by statisticians of the Metropolitan Life Insurance Company. In the corresponding period of 1958 the figure was over 800. Through June of this year there were two disasters in which 25 or more persons lost their lives, both of them involving civil aviation. On Feb. 3, a scheduled airliner crashed into the East River in New York City, causing 65 deaths, and 31 were killed when another scheduled plane disintegrated in mid-air during a thunderstorm near Baltimore on May 12. The loss of life in military aviation catastrophes decreased appreciably, according to the statisticians, reaching one of the lowest points for any comparable period in the last 10 years. Bus accidents in which five or more were killed also took fewer lives this year than last. In contrast, catastrophes involving other types of motor vehicles took a greater toll than a year ago.

Fellowships in Psychiatry.—The American Psychiatric Association will continue its program of fellowships in psychiatry for the current year. The program, made possible by a grant from the Smith, Kline, and French Foundation of Philadelphia is intended "to interest physicians and medical students in psychiatry and mental hospitals and to advance levels of treatment and care in these institutions." Several types of awards are available and applications from individual physicians, medical students, or institutions will be considered so long as they relate to these purposes. The new Seymour D. Vestermark Fellowships, named in honor of the late chief of the Training Branch of the National Institute of Mental Health, are intended to stimulate interest and knowledge in psychiatry among "outstanding" medical students. A brochure describing the program and how to apply will be sent on request to Dr. George N. Raines, Chairman, APA Fellowship Committee, 1700 18th St., N. W., Washington 9, D. C.

Meeting on Deafness.—The Alexander Graham Bell Association for the Deaf will hold its 69th annual summer meeting in Rochester, N. Y., June 27-July 1, 1960, Sol Richard Silverman, Ph.D., St. Louis, president of the association, announced. Mr. James H. Galloway, superintendent of the Rochester School for the Deaf, is general chairman. The program committee is headed by Dr. Leo Connor, assistant superintendent of the Lexington School for the Deaf. Included in the five-day meeting will be panel discussions, demonstrations, film showings, visits to schools for the deaf, and sessions of particular interest to members of the parents' section of the association. An invitation is extended by the association to all professional workers in the education of deaf children to present prepared papers on topics of interest. Topics and outlines must be submitted by Nov. 1 for consideration. Final approval will be sent to each author by the program committee. Outlines may be sent to the Alexander Graham Bell Association for the Deaf, 1537 35th St., N. W., Washington 7, D. C.

Chest Physicians Meeting in Albuquerque.—The American College of Chest Physicians will hold a silver anniversary homecoming meeting in Albuquerque, N. M., Oct. 14-17, with headquarters at the Western Skies Hotel. The program is arranged under the following session headings:

Reports Summarizing Technics and Their Applications in the Study and Treatment of Heart Disease.
Pertinent Aspects in the Study and Treatment of Pulmonary Disease: Anatomy, Pathology, and Physiology.
Unrelated Papers on Special Problems of the Heart, Lungs, and Mediastinum.
Medicine and Surgery: Responsibilities for the Control of Cardiopulmonary Disease.
Unrelated Papers on the Medical Study and Treatment of Cardiac and Pulmonary Disease.
Practical Considerations of Cardiovascular Physiology: Applications in Medicine and Surgery.

Nine round-table luncheon meetings and 22 "fireside conferences" are planned. The banquet will be held Oct. 17, 8 p. m. A program of entertainment and ladies' activities is arranged. For information, write Mr. Murray Kornfield, 112 E. Chestnut St., Chicago 11, executive director.

Grants for Pediatric Studies.—Grants providing for postgraduate pediatric studies will be awarded again in 1960 by Wyeth Laboratories, it has been announced by Dr. Philip S. Barba, Philadelphia, past-president of the American Academy of Pediatrics and chairman of the fellowship selection committee. The Philadelphia Pharmaceutical Manufacturing Company will award 20 two-year grants, each carrying an annual stipend of $2,400. Applications for the fellowships must be submitted by Nov. 30, and the grants will be effective on July 1, 1960. Candidates for the pediatric fellowships may include interns, physicians who have recently completed their internship, military service, or a U. S. Public Health Service Tour, and research fellows. All recipients must be citizens of the United States or Canada. Fellowships will be awarded on the basis of the applicants' "interest in the care and treatment of children, character, conscientious and able performance of duties, and academic competence." Those receiving Wyeth grants may attend any hospital whose residency program is properly accredited by the Residency Review Committee of the American Board of Pediatrics, and the Council on Medical Education of the American Medical Association. Applications may be obtained from Dr. Barba at the University of Pennsylvania School of Medicine, Philadelphia.

Meeting on Ophthalmology and Otolaryngology.—The 64th annual meeting of the American Academy of Ophthalmology and Otolaryngology will be held Oct. 11-16 at the Palmer House, Chicago, under the presidency of Dr. John H. Dunnington, New York City. The 16th annual Jackson Memorial Lecture will be given the morning of Oct. 14 by Prof. Dr. Jules Francois, of the department of ophthalmology of the University of Ghent, Belgium, entitled "Syndromes with Congenital Cataract." Dr. James H. Maxwell, professor of otolaryngology, University of Michigan Medical School, Ann Arbor, will give the 15th Wherry Memorial Lecture, "Chronic Lympho-Epithelial Sialadenopathy." The presidential address, "Interdependence," will be given the morning of Oct. 12, to be followed by "Women and Medicine" by the guest of honor, Dr. Georgiana D. Theobald, emeritus clinical pathologist, University of Illinois College of Medicine, Chicago. Two symposiums are planned for section meetings on ophthalmology: Office Management of the Primary Glaucomas and Corneal Surgery. A panel discussion, "Nasal Polyps," is scheduled for the otolaryngology section, Oct. 15. Special scientific programs will be held in conjunction with the meetings of the Committee on Conservation of Hearing and the Otosclerosis Study Group. For information, write Dr. William L. Benedict, 15 Second St., S. W., Rochester, Minn., Executive Secretary.

Public Health Meeting in Atlantic City.—The 87th annual meeting of the American Public Health Association and meetings of related organizations will be held in Convention Hall, Atlantic City, N. J., Oct. 19-23. Dr. Leona Baumgartner, New York City commissioner of health and president of the association, said that the theme, "Public Health Is One World," has been adopted. World Health Organization officials on the program include Dr. M. G. Candau, Geneva, Switzerland, director-general and Dr. Abraham Horwitz, of Chile, director of the World Health Regional Office for the Americas. Authorities from the following countries will present papers before scientific or general sessions: Denmark, England, Ghana, India, Japan, Soviet Union, Sweden, and Yugoslavia. About 400 scientific papers will be presented in 75 sessions. General sessions will feature presentation of the annual Albert Lasker awards of the American Public Health Association and the Sedgwick Memorial Medal. Scientific sessions, workshops, and scientific and technical exhibits are scheduled. Among organizations holding sessions during the week will be the American School Health Association, American College of Preventive Medicine, American Association of Public Health Physicians, American Industrial Hygiene Association, Industrial Medical Association, National Health Council, Joint Commission on Mental Health and Illness, and the Public Health Cancer Association of America. The American Public Health Association, with headquarters at 1790 Broadway, New York City, has more than 13,500 members. Its executive director is Dr. Berwyn F. Mattison.

Grants for Cancer Research.—Award of 210 grants to support research in 79 institutions in the United States and one in England totaling $4,756,834 was announced by the American Cancer Society. Among the recipients are Nobel Prize winners Selman A. Waksman, Ph.D., New Brunswick, N. Y., who developed streptomycin, and Wendell M. Stanley, Ph.D., Berkeley, Calif., who was the first scientist to crystallize a virus. The grant to support research in England is a postdoctoral fellowship to permit an American to complete his training at the Virus Research Unit of the Agriculture Research Council in Cambridge, England. At the same time, the society announced creation of a committee on tobacco and cancer as a standing committee of the board of directors, replacing its ad hoc committee on smoking and health. Dr. Dean F. Davies, St. Louis, formerly American Cancer Society administrator for research on lung cancer, will be executive secretary of the new committee. The grants announced are the first of a series to be made during the society's fiscal year beginning Sept. 1, and brings the dollar amount of the grants now in effect to more than $15,000,000. Since 1946, the American Cancer Society has awarded more than $71,000,000 for support of research. Among the grants awarded nationally, $1,152,310 is for research on the therapy of cancer. The 50 grants made are for research related to diagnosis and treatment. Nearly as much, $1,150,299, was awarded for 55 grants on the etiology of cancer. Research on the pathogenesis of cancer was supported with 50 grants amounting to $890,480. Fourteen grants for research on lung cancer were awarded amounting to $475,347. Nine postdoctoral fellowships for training in research were awarded at a cost of $118,898. Institutional research grants totaling $939,500 were awarded to 29 institutions.

LATIN AMERICA

Course on Dermatology in Buenos Aires.—A postgraduate course on dermatology will be given by the Asociacion Medica Argentina, Santa Fe, 1171, Buenos Aires, Argentina. This course will consist of theoretical and practical intensive studies on dermatology, under the direction of Dr. Isaac Zelcer, and will start on Nov. 16 and continue to Nov. 21. The basic topics will deal with dermatology in childhood and treatment of dermatologic diseases. Registration will take place at Santa Fe, 1171, Buenos Aires, Argentina. For details, write to this address.

Cuba Recognizes Pan American Confederation.—Dr. Armando Monnar Pérez, chief dispatcher for the Confederacíon Médica Panamericana, has announced that the Revolutionary Government of Cuba made and put into force Law No. 300, dated April 20, 1959, by which the confederation is officially recognized. The ministry of education has given the confederation suitable headquarters. Correspondence to the confederation should be addressed as follows:

Confederacíon Médica Panamericana
Casa de las Americas
Avenida de los Presidentes y 3ra
Vedado—La Habana—Cuba

EXAMINATIONS AND LICENSURE

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES, INC.

Educational Council for Foreign Medical Graduates: Stations around the world. March 16, 1960 and Sept. 21, 1960. Exec. Director, Dr. Dean F. Smiley, 1710 Orrington Ave., Evanston, Ill.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 21-23, 1960. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery.

Alaska:* On application in Anchorage or Fairbanks. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Arizona:* *Examination.* Phoenix, Oct. 14-16. *Reciprocity.* Phoenix, Oct. 17. Ex. Sec., Mr. Robert Carpenter, 826 Security Bldg., Phoenix.

Arkansas:* *Examination and Reciprocity.* Little Rock, Nov. 5-6. Sec., Dr. Joe Verser, Harrisburg.

California: *Written.* Sacramento, October 19-22. *Oral.* San Francisco, November 14. *Oral and Clinical.* San Francisco, Nov. 15. Sec., Dr. Louis E. Jones, Room 536, 1020 N Street, Sacramento.

Colorado:* *Examination.* Denver, Dec. 8-9. *Reciprocity.* Denver, Oct. 14. Exec. Sec., Miss Mary M. McConnell, 715 Republic Bldg., 1612 Tremont Place, Denver 2.

Connecticut:* *Examination.* Hartford, Nov. 10-12. Sec. to the Board, Dr. Stanley B. Weld, 160 St. Ronan St., New Haven.

Delaware: *Examination.* Dover, Jan. 12-14. *Endorsement.* Dover, Jan. 21. Sec., Dr. Joseph S. McDaniel, Professional Bldg., Dover.

District of Columbia:* *Examination.* Washington, Dec. 14-15. *Reciprocity.* Washington, Sept. 14. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave., Washington 6.

Florida:* *Examination.* Miami Beach, Nov. 22-24. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Georgia: *Examination and Reciprocity.* Atlanta, Oct. 13. Sec., Mr. Cecil L. Clifton, 224 State Capitol, Atlanta 3.

Guam: *Subject to Call.* Act. Sec., Dr. F. L. Conklin, Agana.

Idaho: *Examination* and *Reciprocity.* Boise, Jan. 11, 12, 13. Exec. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Indiana: *Examination.* Indianapolis, June 1960. *Reciprocity.* Indianapolis, fourth Wednesday of each month. Ex. Sec., Miss Ruth V. Kirk, 538 K. of P. Bldg., Indianapolis.

Kansas:* *Examination and Reciprocity.* Kansas City, Jan. 15-16. Sec., Dr. F. J. Nash, New Brotherhood Bldg., Kansas City.

Kentucky: *Examination.* Frankfort, Dec. 14-15. Asst. Sec., Mrs. Ray Wunderlich, 620 South Third St., Louisville 2.

Louisiana: *Examination and Reciprocity.* New Orleans, Dec. 3-5. Sec., Dr. Edwin H. Lawson, 930 Hibernia Bank Bldg., New Orleans 12.

Maine: *Examination* and *Reciprocity.* Portland, Nov. 10. Sec., Dr. Stephen A. Cobb, Stanford.

Maryland: *Examination.* Baltimore, Dec. 8-11, Sec., Dr. Frank K. Morris, 1211 Cathedral St., Baltimore 1.

Michigan:* *Examination.* Lansing, Oct. 26-28. Ex. Sec., Dr. E. C. Swanson, 118 Stevens T. Mason Bldg., Lansing.

Minnesota:* *Examination.* Jackson, June 1960. *Reciprocity.* Jackson, Dec. 7, Sec., Dr. A. L. Gray, Old Capitol, Jackson.

Minnesota:* *Examination and Reciprocity.* St. Paul, Oct. 20-22. Sec., Dr. F. H. Magney, 230 Lowry Medical Arts Bldg., St. Paul 2.

Montana: *Examination and Reciprocity.* Helena, Oct. 6. Sec., Dr. Thomas L. Hawkins, 555 Fuller Ave., Helena.

Nebraska:* *Examination.* Omaha, June 13-15, 1960. Dir., Bureau of Examining Boards, Room 1009, State Capitol Bldg., Lincoln 9.

New Jersey: *Examination.* Trenton, Oct. 20-23. *Reciprocity.* Monthly, Sec., Dr. Royal A. Schaaf, 28 West State St., Trenton.

New Mexico:* *Examination and Reciprocity.* Santa Fe, Nov. 16-17. Sec., Dr. C. Derbyshire, 227 East Palace Ave., Santa Fe.

New York: *Examination.* Albany, Buffalo, New York and Syracuse, Dec. 8-11. Sec., Dr. Stiles D. Ezell, 23 South Pearl St., Albany.

North Dakota: *Examination.* Grand Forks, Jan. 6-8. *Reciprocity.* Grand Forks, Jan. 9. Sec., Dr. C. J. Glaspel, Box 228, Grafton.

Ohio: *Examination.* Columbus, Dec. 15-17. *Endorsement.* Columbus, Oct. 5. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Oregon:* *Examination.* Portland, Oct. 22-24. Ex. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland.

Pennsylvania: *Examination.* Philadelphia, January. Sec., Mrs. Margaret G. Steiner, Box 911, Harrisburg.

Texas:* *Examination.* Fort Worth, Dec. 3-5. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Utah: *Examination.* Salt Lake City, July 6-8. *Reciprocity.* Salt Lake City, Nov. 17. Director, Mr. Frank E. Lees, 324 State Office Bldg., Salt Lake City 1.

Virginia: *Examination and Reciprocity.* Richmond, Dec. 2-4. Address: Board of Medical Examiners, 631 First St. S. W., Roanoke.

Virgin Islands: *Examination.* Charlotte Amalie, Nov. 12-13. Sec., Dr. Benjamin Nath, Charlotte Amalie, St. Thomas.

Washington:* *Examination.* Seattle, Jan. 11-13. Administrator, Professional Division, Capitol Bldg., Olympia.

West Virginia: *Examination.* Charleston, January. Sec., Dr. Newman H. Dyer, State Office Bldg., No. 3, Charleston 5.

Wisconsin:* *Examination.* Madison, Jan. 14-16. *Reciprocity.* Madison, Oct. 23. Sec., Dr. Thomas W. Tormey, Jr., 1140 State Office Building, 1 West Wilson St., Madison.

Wyoming: *Examination and Reciprocity.* Cheyenne, Oct. 5. Sec., Dr. James W. Sampson, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: *Examination and Reciprocity.* Juneau, November. Sec., Dr. R. Harrison Leer, Alaska Office Bldg., Juneau.

Connecticut: *Examination.* New Haven, Oct. 10. Exec. Asst., Mrs. Regina G. Brown, 258 Bradley St., New Haven 10.

District of Columbia: *Examination.* Washington, Nov. 23-24. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave., Washington 6.

Florida: *Examination.* Gainesville, Nov. 7. Sec., Mr. M. W. Emmel, Box 340, Gainesville.

Kansas: *Examination.* Pittsburg, Nov. 6-7. Sec., Dr. Leon C. Heckert, Kansas State College, Pittsburg.

Michigan: *Examination.* Ann Arbor and Detroit, Oct. 9-10. Sec., Mrs. Anne Baker, West Michigan Ave., 116 Stevens T. Mason Bldg., Lansing.

Minnesota: *Examination.* Minneapolis, Oct. 6-7. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis.

New Mexico: *Examination.* Santa Fe, Oct. 18, *Reciprocity.* Santa Fe, Oct. 7. Sec., Mrs. M. Cantrell, P. O. Box 1522, Santa Fe.

Rhode Island: *Examination.* Providence, Nov. 18. *Reciprocity.* Providence, Nov. 4. Administrator, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Dakota: *Examination.* Vermillion, Dec. 4-5. Dr. Gregg M. Evans, 310 East 15th St., Yankton.

Texas: *Examination.* Austin, Oct. 12-13. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

Washington: *Examination.* Seattle, Jan. 6-7. Sec., Mr. Thomas A. Carter, Capitol Bldg., Olympia.

Wisconsin: *Examination.* Milwaukee, Dec. 5. Sec., Mr. Wm. H. Barber, 621 Ranson St., Ripon.

---

*Basic Science Certificate required.

GOVERNMENT SERVICES

AIR FORCE

Personal.—Col. James M. Davis, M. C., was recently honored by the Chinese National Air Force with the award of its flight surgeon wings. The award was made in Taipai, Taiwan (Formosa), by Lieut. Gen. HSU, Huan-shen, deputy commander in chief Chinese Air Force. Colonel Davis is presently assigned as director of the professional services for Pacific Air Forces, located at Hickam Air Force Base, Hawaii.

ARMY

Personal.—Major Gen. Elbert DeCoursey, commandant of the Army Medical Service School at Brooke Army Medical Center, received an honorary Doctor of Laws degree from Baylor University in August. The citation praised his contributions to military and medical administration and especially his active interest in pathological research. General DeCoursey also holds the honorary Doctor of Sciences degree from the University of Kentucky, where he took his undergraduate work.

NAVY

Symposium on Environmental Medicine.—The Tenth Annual Military Medico-Dental Symposium on Environmental Medicine for all armed forces of the United States will be held Oct. 28-30, at the U. S. Naval Hospital, Pattison Ave., Philadelphia 45. Members of the medical, dental, and nursing professions, and students, interns, residents, and hospital administrators are cordially invited to attend. Arrangements have been made to award retirement point credits for Army, Air Force, and Naval Reserve officers attending. Address all correspondence to District Medical Officer, Building 4, U. S. Naval Base, Philadelphia 12.

PUBLIC HEALTH SERVICE

Personal.—Dr. Nathaniel I. Berlin was appointed chief, general medicine branch, National Cancer Institute. He has been head of the metabolism service of that branch since his appointment to the staff in November, 1956.——Dr. Glen R. Leymaster, professor and head of the department of preventive medicine at the University of Utah College of Medicine, was appointed to serve a four-year term on the epidemiology and biometry advisory committee of the National Institutes of Health, U. S. Public Health Service.——Dr. Alson E. Braley, professor and chairman of the department of ophthalmology at the State University of Iowa, Iowa City, since 1950, has been reappointed to the National Advisory Neurological Diseases and Blindness Council for a four-year term.

DEATHS

Abbott, C. Norman Ⓜ Cucamonga, Calif.; College of Medical Evangelists, Loma Linda and Los Angeles, 1934; chairman of the board of American Humanics Foundation, of which he was a past-president; member of the American College of Chest Physicians, American Trudeau Society, and the Industrial Medical Association; fellow of the International College of Surgeons; past-president of the San Bernardino County Medical Society; associated with the San Antonio Community Hospital in Upland; died July 18, aged 51.

Abramson, Paul Dowling Ⓜ Shreveport, La.; born in Shreveport March 17, 1906; Tulane University of Louisiana School of Medicine, New Orleans, 1929; specialist certified by the American Board of Surgery; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons and past-president of the Louisiana Chapter; veteran of World War II; clinical professor of surgery at Louisiana State University School of Medicine in New Orleans; past-president of the Louisiana State Medical Society and the Shreveport Medical Society; on the staffs of the Confederate Memorial Medical Center and North Louisiana Sanitarium; formerly co-editor of the *Tri-State Medical Journal;* died July 18, aged 53.

Auld, Douglas De Vallee Ⓜ Sandusky, Ohio; University of Western Ontario Faculty of Medicine, London, Ont., Canada, 1925; member of the Industrial Medical Association; chief physician for the Ford Motor Company; died in the Cleveland Clinic Hospital July 20, aged 62.

Ballenger, William Lee, Atlanta, Ga.; Atlanta College of Physicians and Surgeons, 1912; for many years on the faculty of the Atlanta Dental College; died in Milledgeville July 17, aged 78.

Bausch, Robert Peter, Columbus, Ohio; Ohio State University College of Medicine, Columbus, 1916; veteran of World War I; formerly medical examiner for the Pennsylvania Railroad; died in the Mercy Hospital July 17, aged 66.

Bonner, Clarence Alden Ⓜ Prides Crossing, Mass.; University of Vermont College of Medicine, Burlington, 1913; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; veteran of World War I; formerly associated with the Worcester (Mass.) State Hospital and Warren (Pa.) State Hospital; served as executive officer at the Boston Psychopathic Hospital and as superintendent of the Danvers State Hospital in Hawthorne; at one time assistant to the commissioner of the department of mental diseases for the state of Massachusetts; served on the editorial staff of the *Mental Health Sentinel;* died July 27, aged 71.

Bralliar, John Seward, Franklin, Ky.; University of Tennessee College of Medicine, Memphis, 1939; interned at the French Hospital in San Francisco; veteran of World War II; member of the Simpson County Board of Health; died July 11, aged 50.

Bray, William Edward Ⓜ Charlottesville, Va.; born in Winona, Miss., March 7, 1882; University of Virginia Department of Medicine, Charlottesville, 1912; specialist certified by the American Board of Pathology; past-president of the Virginia Society for Pathology and Laboratory Medicine; founding fellow of the College of American Pathologists and member of the American Society of Clinical Pathologists; served on the faculty of his alma mater, where he was director of clinical laboratories; professor of pathology and bacteriology at the University of Mississippi School of Medicine in University, 1914-1915; epidemiologist for the state health department of Virginia during the summers from 1910 to 1914; on the staff of the Martha Jefferson Hospital; author of "Clinical Laboratory Methods" and "Synopsis of Clinical Laboratory Methods"; died July 18, aged 77.

Brown, H. Ernest, Roanoke, Va.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1914; served in the Royal Army Medical Corps during World Wars I and II; chief of psychiatry and mental hygiene clinic of the Veterans Administration Hospital and regional office; died July 15, aged 65.

Bryant, John B., Chicago; Meharry Medical College, Nashville, Tenn., 1913; at one time practiced in Stuttgart, Ark.; died July 20, aged 73.

Bundrant, Herschel Belmont, Detroit; Indiana University School of Medicine, Indianapolis, 1936; died July 9, aged 47.

Burbach, William Martin Ⓜ Chicago; Northwestern University Medical School, Chicago, 1905; died July 18, aged 81.

Burnham, Arthur F., Metamora, Mich.; Detroit College of Medicine, 1903; died in Lapeer July 12, aged 80.

Ⓜ Indicates Member of the American Medical Association.

Burwig, William Herbert Ⓜ Buffalo; University of Buffalo School of Medicine, 1923; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the International College of Surgeons and the American College of Surgeons; associated with Millard Fillmore, Deaconess, Buffalo General, and Children's hospitals; died April 16, aged 59.

Chapman, James Aubrey Ⓜ Alexander City, Ala.; Medical College of Alabama, Mobile, 1905; associated with the Russell Hospital; died July 14, aged 79.

Clements, Albert Fred, Evansville, Ind.; Rush Medical College, Chicago, 1920; past-president of the Vanderburgh County Medical Society; veteran of World Wars I and II; died July 9, aged 64.

Compton, Charles Wentworth Ⓜ Springfield, Ill.; Central College of Physicians and Surgeons, Indianapolis, 1900; on the staffs of St. John's and Memorial hospitals; died July 6, aged 83.

Cook, William Henry Ⓜ Chickasha, Okla.; Washington University School of Medicine, St. Louis, 1907; served as chief surgeon for the Frisco Railroad for many years; died in the Chickashaw Hospital July 12, aged 81.

Crane, Harley C., Flint, Mich.; Detroit College of Medicine and Surgery, 1929; veteran of World War I; died July 14, aged 65.

Crothers, Bronson, Cambridge, Mass.; Harvard Medical School, Boston, 1910; member of the American Pediatric Society, of which he was past-president, American Academy of Pediatrics, American Neurological Association, and the Association for Research in Nervous and Mental Diseases; served on the faculty of his alma mater; on the staff of the Children's Hospital; veteran of World War I; author of "Disorders of the Nervous System in Childhood" and "A Pediatrician in Search of Mental Hygiene"; died in his summer home in Sorrento, Maine, July 17, aged 75.

Crume, William Keith Ⓜ Bardstown, Ky.; University of Louisville School of Medicine, 1934; interned at the Louisville City Hospital, where he served a residency; member of the American Academy of General Practice; member of the city council; served as a member of the board of education and the Nelson County Health Department; a director of the Farmers Bank & Trust Company; associated with the Flaget Memorial Hospital, where he died July 10, aged 53.

Culver, Harry Ⓜ Chicago; Rush Medical College, Chicago, 1913; specialist certified by the American Board of Urology; member of the American Association of Genito-Urinary Surgeons and the American Urological Association; fellow of the American College of Surgeons; chairman, Section on Urology, American Medical Association, 1933-1934; formerly associated with the U. S. Public Health Service; served as chief of the department of urology at Cook County and St. Luke's hospitals; died while on a vacation in Gleneagles, Scotland, Aug. 5, aged 73.

Currie, George Alexander Wilson, Toronto, Ont., Canada; born in Picton Nov. 20, 1913; Queen's Faculty of Medicine, Kingston, Ont., 1938; interned at Regina General Hospital in Regina, Sask.; veteran of World War II; past-president of the Colorado Hospital Association; a member of the American Hospital Association, American College of Hospital Administrators, and the American Public Health Association; formerly assistant hospital administrator at St. Luke's Hospital in New York City; on the faculty of the University of Colorado School of Medicine and on the staff of the Colorado General Hospital in Denver; later accepted an appointment at the University of Texas Medical Branch in Galveston, Texas, resigning in 1957, when he became superintendent of the Hospital for Sick Children; died while vacationing at a lodge near Picton, Ont., July 16, aged 45.

Darrow, Anna A. Ⓜ Coral Gables, Fla.; Chicago College of Medicine and Surgery, 1909; died July 22, aged 82.

Davis, Carl Lawrence, Hillsdale, Mich.; born in Vermontville, July 9, 1878; Columbian University Medical Department, Washington, D. C., 1903; retired in 1948 after 29 years as professor of anatomy at the University of Maryland School of Medicine in Baltimore; served on the faculty of his alma mater, now known as the George Washington University School of Medicine, as demonstrator in anatomy from 1912 to 1914 and as professor of anatomy from 1914 to 1919; member of Phi Sigma, the Society of Sigma Xi, American Association for the Advancement of Science, and the American Association of Anatomists; died in the Hillsdale Health Center July 13, aged 81.

Dickson, Green Knowlton, Oklahoma City, Okla.; Washington University School of Medicine, St. Louis, 1922; died in the Veterans Administration Hospital July 11, aged 62.

Drues, Isadore Abraham Ⓜ Tacoma, Wash.; University of Illinois College of Medicine, Chicago, 1923; died in the Tacoma General Hospital July 16, aged 60.

Ellis, Frank Alberson Ⓜ Corpus Christi, Texas; University of Pennsylvania School of Medicine, Philadelphia, 1918; specialist certified by the American Board of Urology; veteran of World War II; served as secretary and treasurer of the North Carolina Urological Society; while practicing in Salisbury, N. C., served a term as president of the Rowan County Medical Society; on the staffs of the Crippled Children's, Memorial, and Spohn hospitals; died in the Veterans Administration Hospital, Houston, July 12, aged 65.

Epps, Curtis Howard Ⓜ Springfield, Mo.; Washington University School of Medicine, St. Louis, 1936; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; veteran of World War II; on the staffs of the Burge Hospital, St. John's Hospital, and Springfield Baptist Hospital; local surgeon for the Frisco Railroad; died in the Barnes Hospital, St. Louis, July 17, aged 47.

Farley, Hiram H. Ⓜ Logan, W. Va.; Hospital College of Medicine, Louisville, 1904; served as a member of the city council; formerly medical director of the Mercy Hospital, now known as Guyan Valley Hospital; died July 18, aged 80.

Fowler, Wirt Dee, Eden, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1909; served overseas during World War I; died in Austin July 7, aged 77.

Frey, Conrad, Las Vegas, N. M.; University of Texas School of Medicine, Galveston, 1913; served on the staff of the Wichita Falls (Texas) State Hospital; on the staff of the New Mexico State Hospital; died July 10, aged 83.

Friedlander, Emil Ⓜ Cincinnati; Universität Rostock Medizinische Fakultät, Rostock, Mecklenberg, Germany, 1918; member of the American Academy of Dermatology and Syphilology; instructor of dermatology at the University of Cincinnati College of Medicine; on the staffs of the Cincinnati General and Jewish hospitals; died July 8, aged 68.

Harris, Clarence P. Ⓜ Houston, Texas; Loyola University College of Medicine, Chicago, 1916; specialist certified by the American Board of Radiology; fellow of the American Roentgen Ray Society and the American College of Radiology; veteran of World War I; associated with the Jefferson Davis Hospital, St. Joseph Hospital, and the Huntsville (Texas) Memorial Hospital; died July 19, aged 65.

Hausner, Erich P. Ⓜ Santa Fe, N. M.; born Aug. 1, 1905; Deutsche Universitat Medizinische Fakultat, Prague, Czechoslovakia, 1929; specialist certified of the American Board of Internal Medicine; veteran of World War II; served a fellowship at the Mayo Foundation in Rochester, Minn.; from 1933 to 1935 assistant professor of medicine at his alma mater; past-president of the New Mexico Society of Internal Medicine; associated with the Los Alamos Medical Center in Los Alamos, Espanola (N. M.) Hospital, St. Vincent's Hospital in Santa Fe, and St. Anthony's Hospital in Las Vegas; consultant in medicine at the Veterans Administration Hospital in Albuquerque; died in Beaulieu-Sur-Mer, France; July 2, aged 54.

Hofmann, Andrew Ⓜ Hammond, Ind.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1909; served as coroner of Lake County; on the honorary staff of the St. Margaret Hospital, where he died July 9, aged 81.

Horton, Charles Bertram, New York City; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1925; member of the American Psychiatric Association; veteran of World Wars I and II; at one time associated with the State School for Boys at Meriden, Conn.; died July 17, aged 60.

Houser, Oscar Julian Ⓜ Charlotte, N. C.; North Carolina Medical College, Charlotte, 1914; associated with Charlotte Memorial Hospital; died in the Mercy Hospital July 21, aged 74.

Hughes, Bernard, New York City; New York Homeopathic Medical College and Flower Hospital in New York City, 1918; veteran of World War I; deputy superintendent, Kings County Hospital; died in the Veterans Administration Hospital in Brooklyn July 24, aged 77.

Hyde, Robert Dwight Ⓜ Beverly Hills, Calif.; Harvard Medical School, Boston, 1927; certified by the National Board of Medical Examiners; associated with Santa Monica Hospital and St. John's Hospital in Santa Monica, where he died July 15, aged 63.

Jackson, Kenna Ⓜ Clarksburg, W. Va.; College of Physicians and Surgeons, Baltimore, 1913; for many years county coroner; died July 16, aged 77.

Jacobs, Benjamin C. Ⓜ Los Angeles; Cornell University Medical College, New York City, 1923; assistant clinical professor of psychiatry at the College of Medical Evangelists in Loma Linda and Los Angeles; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; served on the staffs of the Metropolitan State Hospital in Norwalk, Los Angeles County General Hospital, and White Memorial Hospital; died July 18, aged 62.

Jones, Thomas Glenn, Hyattsville, Md.; National University Medical Department, Washington, D. C., 1902; died April 28, aged 83.

Kalish, John Theophil Ⓜ Baltimore; Schlesische Friedrich Wilhelms-Universität Medizinische Fakultät, Breslau, Prussia, Germany, 1924; interned at the Madison Park Hospital in Brooklyn; served a residency at the Kingston Avenue Hospital in Brooklyn and the Robert Koch Hospital in Koch, Mo.; member of the American Trudeau Society;

associated with the Veterans Administration Hospital; died in the Johns Hopkins University Hospital July 9, aged 58.

Kennedy, Andrew Aloysius, Clifton, N. J.; Temple University School of Medicine, Philadelphia, 1923; veteran of World Wars I and II; for many years associated with the Veterans Administration; on the staffs of the Veterans Administration Hospital in East Orange, where he died July 15, aged 66.

Kerr, George Kenneth, Staten Island, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1928; veteran of World War II; on the staff of St. Vincent's Hospital; died July 2, aged 56.

King, William Scott, Green Bay, Wis.; Northwestern University Medical School, Chicago, 1911; for many years practiced in Eveleth, Minn., where he was school physician; died July 17, aged 72.

Koerber, Lillie Louise, San Francisco; Cooper Medical College, San Francisco, 1906; died in July, aged 80.

Koreski, Benjamin Clarence Ⓜ Yakima, Wash.; St. Louis University School of Medicine, 1932; past-president of the Yakima County Medical Society; fellow of the American College of Surgeons; staff member, St. Elizabeth's and Yakima Valley Memorial hospitals; died in the University of Washington Hospital in Seattle, July 9, aged 65.

Landry, Lucian Hyppolite Ⓜ New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1907; member of the founders group of the American Board of Surgery; member of the Southern Surgical Association, of which he was formerly vice-president; for many years on the faculty of his alma mater; fellow of the American College of Surgeons; consultant at the Touro Infirmary and Charity Hospital of Louisiana; past-president of the Tulane Alumni Association; died July 11, aged 76.

Landsman, Arthur Armin Ⓜ New York City; Cornell University Medical College, New York City, 1900; also a graduate in pharmacy; senior fellow of the American Proctologic Society; past-president of the New York State Proctologic Society; for many years president of the medical board of the Jewish Memorial Hospital, where he was attending physician and consultant in proctology; died in the Beth Israel Hospital July 31, aged 85.

Lang, Herbert Bowman, South Hadley, Mass.; Harvard Medical School, Boston, 1902; served as chairman of the board of health and school physician; at one time on the board of water commissioners for Fire District Number 2; on the courtesy staffs of Holyoke and Providence hospitals in Holyoke; died July 24, aged 85.

Latta, Philip Rankin Ⓜ La Grange, Ill.; University of Illinois College of Medicine, Chicago, 1937; specialist certified by the American Board of Dermatology and Syphilology; fellow of the American Academy of Dermatology and Syphilology; veteran of World War II; on the staffs of the Community Memorial General Hospital in La Grange and the Hinsdale (Ill.) Sanitarium and Hospital, where he died July 17, aged 48.

Leggett, Lindley Hoag Jr. Ⓜ Westfield, N. J.; New York Homeopathic Medical College and Hospital, New York City, 1918; member of the board of health; associated with the Muhlenberg Hospital in Plainfield; died in Pemaquid Point, Maine, July 22, aged 64.

Leslie, William Francis, Hilo, Hawaii; Indiana University School of Medicine, Indianapolis, 1928; past-president of the Hawaii County Medical Society; superintendent of the Puumaile–Hilo Memorial Hospital, where he died July 4, aged 56.

Lettinga, Dirk, Grant, Mich.; Grand Rapids Medical College, 1907; past-president of the Grant village; village councilman for 38 years; served as health officer and secretary treasurer of the school board; a trustee of the Grant Chamber of Commerce; died in the Grant Community Hospital July 10, aged 83.

Long, Frank Leo Ⓜ Los Angeles; Washington University School of Medicine, St. Louis, 1904; veteran of World War I; chief regional medical officer of the Veterans Administration; retired Nov. 30, 1952; at one time on the staff of State Hospital in Farmington, Mo.; died in Hollywood Presbyterian Hospital July 9, aged 76.

Lynch, John Patrick Ⓜ Pawtucket, R. I.; Long Island College of Medicine, Brooklyn, 1905; died in the Memorial Hospital July 4, aged 79.

McCannel, Archibald Duncan Ⓜ Minot, N. D.; born in Chesley, Ont., Canada, June 3, 1879; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1906; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow and past-governor of the American College of Surgeons; past-president of the North Dakota State Medical Association, of which he was past-vice-president; served as a member of the state board of medical examiners; past-president of the board of the YMCA; formerly member of the North Dakota Public Welfare Board; received the Silver Beaver award for outstanding service to the Boy Scout program; from 1940 to 1947 president of the First National Bank and served as chairman of the board; associated with the St. Joseph's and Trinity hospitals; in 1954 received the honorary doctor of science degree from Jamestown (N. D.) College, serving on its board of trustees for many years; died July 22, aged 80.

McGuire, John W. Ⓜ Neodesha, Kan.; University Medical College of Kansas City, Mo., 1905; associated with Wilson County Hospital as chief of staff; charter member of the Neodesha Lions Club, serving as its first president; a director of the First National Bank of Neodesha; died July 16, aged 79.

Marlatt, Harry R. Ⓜ Fairport, N. Y.; born in Troupsburg, N. Y., June 26, 1885; University of Buffalo School of Medicine, 1911; interned at the Monroe County Hospital in Rochester, N. Y.; practiced in Honeoye Falls, N. Y., where he served as health officer, coroner's physician, and surgeon for Lehigh Valley Railroad; for many years field agent with U. S. Public Health Service in the state of Louisiana; formerly medical director of hospitals at Pennsylvania Ordnance Works in Williamsport, and Kankakee Ordnance Works in Joliet, Ill.; served as burgess of Montgomery and as school physician of Lycoming County, Pa.; director of the Peoria County Tuberculosis Association; member of the American School Health Association, Illinois Public Health Association, Mississippi Valley Medical Society, and the Peoria Chamber of Commerce; recipient of the Congressional Medal for Selective service work during World War II; in 1946 was named health officer of the newly organized full-time Peoria County health unit and served until 1951; retired in 1955 as institutional health officer, Peoria State Hospital; died July 13, aged 74.

Mayher, John William Ⓜ Columbus, Ga.; Northwestern University Medical School, Chicago, 1934; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; associated with St. Francis Hospital and the Medical Center; died July 11, aged 50.

Mengis, Christopher Ludwig, Opelousas, La.; born July 11, 1877; Medical Department of Tulane University of Louisiana, New Orleans, 1900; specialist certified by the American Board of Preventive Medicine; director of St. Landry Parish health unit for 15 years; part-time director of Evangeline Parish Health Unit, Ville Platte, La.; past-president of the state board of health; served as assistant state health officer and director of the division of local health service, state board of health; president of the local Chapter for Crippled Children and Adults; past-president of the Louisiana Public Health Association and the Louisiana Conference of Social Welfare; formerly director of the Franklin Parish health unit and the Iberia Health unit; veteran of World War I; fellow of the American Public Health Association; charter member of the American Association of Public Health Physicians; an honorary staff member of the Opelousas General Hospital; died July 10, aged 81.

Messmore, Walter Teed, Uniontown, Pa.; University of Maryland School of Medicine, Baltimore, 1901; died in the Uniontown Hospital July 23, aged 81.

Meyer, Karl George Moritz, New York City; Universität Rostock Medizinische Fakultät, Rostock, Mecklenberg, Germany, 1904; died June 7, aged 79.

Miller, Robert Francis Ⓜ Portland, Ore.; University of Oregon Medical School, Portland, 1935; specialist certified by the American Board of Internal Medicine; veteran of World War II; served on the faculty of his alma mater; associated with Providence Hospital and St. Vincent's Hospital, where he died July 11, aged 50.

Miner, Charles Howard Ⓜ Wilkes-Barre, Pa.; born in Wilkes-Barre, July 5, 1868; University of Pennsylvania Department of Medicine, Philadelphia, 1893; veteran of the Spanish-American War; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the American Clinical and Climatological Association; past-president of the Luzerne County Medical Society; one of the founders of the National Tuberculosis Association and of the Pennsylvania Tuberculosis and Health Association, of which he was the 13th president; instrumental in founding of the Wyoming Valley Tuberculosis Society, of which he was president and later president emeritus; formerly secretary of the state board of health; at one time medical director of Luzerne County; helped in planning the establishment of the Kirby Health Center, and served as first secretary of the board and in 1943 was elected president; named president emeritus at his retirement; in recognition of his long and active career in the health field and leadership in the fight against tuberculosis, the Pennsylvania State Tuberculosis Sanatorium number 3 in Hamburg, Pa., was renamed the Charles H. Miner State Hospital; consulting physician at the Wilkes-Barre General Hospital; served on the staffs of the White Haven (Pa.) Sanatorium, where a ward was named in his honor, and the Mercy Hospital; died July 12, aged 91.

Mitchell, Ralph Cadwallader Ⓜ Sophia, W. Va.; Maryland Medical College, Baltimore, 1902; honorary life member of the West Virginia State Medical Association; veteran of the Spanish-American War and World War I; died in the Beckley (Va.) Hospital July 26, aged 80.

Moeller, Carl Emil Ⓜ St. Louis; Washington University School of Medicine, St. Louis, 1903; associated with Alexian Brothers Hospital and the Lutheran Hospital, where he died July 16, aged 80.

Moolten, Ralph Rembrandt, New York City; Columbia University College of Physicians and Surgeons, New York City, 1919; fellow of the American

College of Surgeons; veteran of World War II; a medical expert for the workmen's compensation division of the city's law department; associated with the New York Postgraduate Medical School and Hospital; on the staff of the University Hospital; died July 20, aged 62.

Morehouse, James Amos Ⓜ Sterling, Colo.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; associated with Logan County Hospital and St. Benedict Hospital; died July 18, aged 76.

Moyes, George Gowans Ⓜ Ogden, Utah; Northwestern University Medical School, Chicago, 1911; past-president of Weber County Medical Society; on the staffs of St. Benedict's Hospital and Thomas D. Dee Memorial Hospital, where he died July 16, aged 80.

Murray, Vance Bishop Ⓜ Guerneville, Calif.; Columbia University College of Physicians and Surgeons, New York City, 1911; died July 12, aged 71.

Musgrave, Robert G., Oakland, Calif.; Kansas City (Mo.) Medical College, 1889; died in Modesto July 3, aged 92.

Nelson, Paul Oscar Ⓜ Emmetsburg, Iowa; State University of Iowa College of Medicine, Iowa City, 1919; died July 7, aged 65.

Norton, Ethelbert Moses Ⓜ Birmingham, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1914; member of the American Academy of General Practice; died July 10, aged 74.

Oesterreicher, Donald Lawson Ⓜ Norman, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1949; interned at the University Hospitals in Oklahoma City, where he served a residency; associated with the Central State Hospital and the Norman Municipal Hospital, where he died July 7, aged 37.

Oldenburg, Alfred Vernor, Chicago; Jenner Medical College, Chicago, 1906; died July 20, aged 77.

Peacock, Thomas Gerald, Milledgeville, Ga.; Harvard Medical School, Boston, 1921; veteran of World War I; member of the American Psychiatric Association; superintendent emeritus of the Milledgeville State Hospital, where he was medical superintendent for many years; died July 13, aged 63.

Perry, Frank O., Norwood, Ohio; Medical College of Ohio, Cincinnati, 1899; formerly city health officer; died in the Good Samaritan Hospital July 8, aged 85.

Quiring, Walter Otto Ⓜ Hutchinson, Kan.; University of Kansas School of Medicine, Kansas City, 1913; specialist certified by the American Board of Otolaryngology; veteran of World War I; past-president of the Reno County Medical Association; associated with St. Elizabeth Mercy Hospital and Grace Hospital, where he died July 6, aged 72.

Rabens, Isidore, Lynwood, Calif.; Rush Medical College, Chicago, 1916; formerly practiced in Chicago, where he was on the faculty of the University of Illinois College of Medicine and on the staffs of Cook County and Mount Sinai hospitals; died in St. Francis Hospital July 15, aged 69.

Richey, Sidney Moore Ⓜ Tulsa, Okla.; St. Louis College of Physicians and Surgeons, 1895; retired surgeon for the Frisco Railroad; died July 10, aged 90.

Robbins, Charles Pern Ⓜ Winona, Minn.; Jefferson Medical College of Philadelphia, 1894; first president of the Winona County Public Health Association; for many years city school physician and Winona County physician; associated with the Winona General Hospital; died July 15, aged 86.

Schrader, Edwin Frederick Ⓜ Macomb, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; died in Peoria July 2, aged 80.

Taylor, Ruth Elaine Ⓜ Chicago; Rush Medical College, Chicago, 1924; served with the student health service at the University of Chicago; for many years on the staff of the Albert Merritt Billings Hospital; died in the Buffalo (N. Y.) General Hospital July 18, aged 63.

Thompson, Cecil Frank, Phillips, Maine; Tufts College Medical School, Boston, 1926; on the staff of the Franklin County Memorial Hospital in Farmington, where he died July 9, aged 59.

Wagner, Charles Andrew Ⓜ Pasadena, Calif.; Jefferson Medical College of Philadelphia, 1934; veteran of World War II; on the staffs of the Alta Vista and Collis P. and Howard Huntington Memorial hospitals; died in St. Luke's Hospital July 14, aged 50.

Wallace, Richard Hendrickson Ⓜ Brookline, Mass.; Harvard Medical School, Boston, 1927; fellow of the American College of Surgeons; served on the faculty of his alma mater; certified by the National Board of Medical Examiners; specialist certified by the American Board of Surgery; served on the staffs of the Massachusetts General Hospital in Boston and the Pondville Hospital in Walpole; consultant at the Massachusetts Eye and Ear Infirmary, Boston; died in Boston July 8, aged 58.

White, James Franklin, Baltimore; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1923; died June 24, aged 58.

FRANCE

Gamma Globulin and Peptic Ulcer.—R. Cavaillo (*Archives des Maladies de l'Appareil Digestif*, Dec., 1958) treated 1,000 patients who had gastric ulcer with convalescent serum. He gave four intramuscular injections of 20 cc. each weekly, followed by maintenance treatment consisting of one injection of 20 cc. every three months for three years. The results were excellent even in those who were emaciated due to renal or cardiac complications or tuberculosis. In view of the difficulty of standardizing this treatment because of the inconstant activity of the serum, the fact that it can be kept for only a few months, and the risk of transmitting viral hepatitis, the author treated the next 46 patients who had gastric ulcer with standard gamma globulins. He gave three intramuscular injections weekly of 10 cc. each. The results in most patients were excellent although less constant than those obtained with the serum. The author concluded that either most donors had a natural antiulcerous substance in their serum or that among the more than 1,000 donors some had healed ulcers and their serum possessed a specific antiulcerous action. The author made further studies with gamma globulins obtained from plasma of patients with healed or healing ulcers and found that the activity of these gamma globulins was about five times as effective as that of standard gamma globulin.

Electrocardiogram After Clinical Death.—K. Saracoglu (*Archives des Maladies du Coeur et des Vaisseaux*, March, 1959) studied the electrocardiograms of 30 persons during and after clinical death. The electric activity of the heart continued after beating of the heart and respiration stopped. Death of the heart started with the lengthening of the PQ interval, then the P wave disappeared, which was a sign of sinoauricular block. The normal systolès were replaced by substitute systoles. The sinus continued its electrical activity until the anatomic death of the myocardium. The alteration of the conductive system was revealed by the prolongation of the QRS complex, which became biphasic. These changes were due to a decrease in metabolism and an increase of the serum carbon dioxide concentration. Foci of infarction sometimes preceded clinical death. Electrical activity might continue for 1 to 40 minutes. In patients who died of noncardiac causes there were terminal complex noncharacteristic monophasic waves, and in those who died of cardiac diseases chaotic tracings and ventricular fibrillation occurred. Intracardiac injections of epinephrine generally failed in patients with cardiac disease, because it provoked ventricular fibrillation. This was not always the case in persons who died of other causes. The author concluded that the difficulty in reanimation was due to the rapid degeneration of the myocardium.

Anuria in Carbon Tetrachloride Poisoning.—Prof. J. Hamburger (*Acquisitions Médicales Récentes*, 1958) stated that anuria due to carbon tetrachloride poisoning is often misdiagnosed. Of 571 patients with anuric nephrosis treated at the Necker Hospital, 25 were due to this poisoning, 6 were caused by trichloroethylene poisoning, and only 17 had nephrosis caused by mercurials. Of these 25 patients, 12 illnesses were due to the professional use of carbon tetrachloride in the workshop and 8 to the domestic use of carbon tetrachloride products for cleaning. In nine patients alcoholic intoxication aggravated the condition.

The author advised that roentgenograms of the chest be made in order to discover latent pulmonary edema. Of the 25 patients, a correct diagnosis was made only in 2. In the other 23 the initial diagnosis included hepatobiliary disease, infection, and pneumonopathy. The duration of anuria was 5 to 14 days. In relation to treatment the danger of the water-salt overload led the author to attempt to obtain a negative fluid balance by limiting and sometimes temporarily withdrawing all fluid intake. On the other hand, during the anuric phase sodium chloride by any route was contraindicated even if the serum level of this salt was low. In eight of the patients the intensive humoral disturbances made extrarenal dialysis necessary. This procedure was indicated by an increase in the level of blood urea which exceeded 3.5 Gm. per liter. Of the 25 patients 24 were cured and 1 died of cirrhosis of the liver.

Staphylococcic Vaginitis.—In the Dec. 12, 1959, issue of *Revue Francaise de Gynécologie et d'Obstétrique*, J. Bret and co-workers reported that of 623 patients with vaginitis 145 (24.7%) were due to staphylococci, showing the same frequency as vaginitis due to trichomonas. The clinical forms were not suggestive of bacterial infection. Some patients had vaginal ulceration or vulvoanal pyodermatitis and a urinary syndrome. The prognosis was worse

The items in these letters are contributed by regular correspondents in the various foreign countries.

in pregnant women. In such patients episiotomy may be complicated by separation of the perineal sutures, cesarean section may be followed by a fatal infection, and otherwise normal delivery may be followed by mammary and urinary infections. In the newborn infant, infection of the umbilical cord, conjunctiva, and respiratory tract may occur. Vaginitis due to staphylococci in all of these patients was resistant to antibiotics.

GERMANY

The Intestinal Electrogram.—The prerequisites of electrographic diagnosis of the intestine were studied by Tiemann and Reichertz (*Med. Klin.* 54:654, 1959) on rats, guinea pigs, and cats under urethan or chloralose-urethan anesthesia. With the use of action-current pictures they succeeded in representing the motility of the intestinal canal in the form of variations of potential by electrography. The curves obtained are termed electrointestinograms (EIG). Vagomimetics, vagolytics, arecoline, carbachol, and atropine, given parenterally, were found to affect the curves. Atropine abolished the changes due to carbachol. The effect of papaverine was less distinct. Barium sulfate had no effect. Clinical examinations of sick and healthy persons gave similar results. Various types of waves could be distinguished: N, C, D, and E, corresponding to normal, hypermotor, stenotic, and dissociated motor conditions. The curves derived from three abdominal points were clearly altered in some intestinal diseases. A gastric carcinoma had wave type C, hypermotility of the small intestine type D, and recent duodenal ulcer associated with spasm and enteric processes corresponded to type E. The EIG provides only a functional diagnosis of the intestinal canal. It is not an aid in the early diagnosis of carcinoma.

INDIA

Tuberculous Meningitis.—A. M. Sur and co-workers concluded from a study of 133 patients with tuberculous meningitis that the lower the level of consciousness at the onset of the disease, the higher the death rate. Other factors that influenced the prognosis were the presence of secondary infection and the development of hydrocephalus and subarachnoid block, all of which were associated with a poor prognosis. Reactivation of the disease often occurred with premature cessation of bed rest before the signs of activity of the disease had subsided completely.

Streptomycin combined with isoniazid was the usual treatment. Cortisone was given to patients who (1) were seriously ill at the onset, (2) showed a poor response to treatment, or (3) showed a sudden deterioration or threatened subarachnoid block. The streptomycin was given intraventricularly instead of intrathecally to patients with subarachnoid block. Tuberculin or streptokinase was given intrathecally to those with threatened block. Vasodilators were helpful in three patients in preventing complete optic atrophy, but failed to do so in one. The general survival rate was 39.6%. Sequelae among survivors were blindness in seven, hemiparesis in three, facial palsy in three, mental deficiency in one, and moon facies with hirsutism in three, two of whom received cortisone. Of 52 survivors 22 could be followed up. Twenty were alive, two had relapses (one of these died and the other was in the ward when last seen).

Failure to demonstrate acid-fast bacilli (AFB) in the cerebrospinal fluid does not exclude tuberculous meningitis as revealed by two patients in this series with such negative findings when the AFB could be demonstrated in exudates in the ventricles or base of the brain, at autopsy, or at operation. The survival rate in patients treated intrathecally with streptomycin and isoniazid was 37.1% as compared with 73% in those who received only intramuscular doses of streptomycin with large doses of isoniazid. The incidence of such complications as pyogenic meningitis and subarachnoid block was also higher when streptomycin was given intrathecally.

Phosphatase Activity of Escherichia Coli.—C. M. Rangam and co-workers (*Indian Journal of Medical Sciences*, vol. 13, June, 1959) studied the phosphatase activity of Escherichia coli to determine the frequency with which phosphatase-producing organisms are found and whether the ability to produce this enzyme depends on the source from which the organisms are obtained. They also tried to find out if any correlation exists between phosphatase production and pathogenicity. Eighty-five strains of Esch. coli from stools of normal healthy persons, from persons who had enteritis, from urinary cultures, and from laboratory stock cultures were used to make dermonecrotic tests. They were also tested for the production of hemolysin. All but one strain of the organism yielded positive tests for phosphatase production, irrespective of their source. Dermonecrosis was obtained with 19 strains and showed no relation to phosphatase production or intensity of phosphatase activity; 30 strains showed hemolytic activity and 9 of these gave positive dermonecrotic tests. Thus, pathogenicity in skin was found to have no relation to phosphatase production and hemolytic activity with regard to Esch. coli.

Trachoma Week.—Trachoma week, organized by the sight conservation committee of the Lions Club of Bombay, was inaugurated on July 4. During the week about 5,000 pupils in selected schools were examined by about 20 ophthalmologists who offered their services free. After being examined each child was given a card showing the condition of his eyes. The card will indicate if the child's eyes are diseased in order that proper treatment can be given in time. The mayor, inaugurating the week, said he was happy to see that clubs generally devoted to relaxation of members were turning into service organizations.

Typhoid in Children.—S. S. Manchanda and co-workers (*Indian Journal of Child Health,* vol. 8, June, 1959) analyzed a series of 270 children with typhoid. Only those with a positive blood culture or a rising agglutination titer were included for study. The incidence was highest from May to October. The most common age group to be involved was 5 to 10 years. In 4.44% of the patients marked cerebral and meningeal symptoms were present at the onset, and meningitis and encephalitis could be excluded only after examination of the spinal fluid. A single relapse occurred in 34, and relapses occurred twice in 2 patients. Leukopenia was present in only 21.9%; in 22.8% there was leukocytosis. A Widal test was done on 266 patients. In 239 patients it was positive with a rising titer. No relation was observed between the duration of illness and the peak of the agglutination titer. All patients in this series were treated with chloramphenicol. Toxic effects on the hemopoietic system were entirely absent even in patients with a low leukocyte count. Their count increased steadily as the toxemia was controlled. Prednisolone was given to 14 patients. Except in three who developed perforation the results of this treatment were good. The death rate was 5.2% and was highest in the group aged 2 to 5 years. None of the five patients who had an intestinal perforation recovered. No relationship was found between blood count and response to treatment. The prognosis was also unaffected by a positive or negative blood culture after the first week.

Bronchodilator Action of Local Anesthetics.—Singh and Sharma (*Indian Journal of Medical Sciences,* vol. 13, June, 1959) studied the bronchodilator action of five local anesthetics synthesized recently on dog's tracheal muscle preparations. Three of the compounds were also studied on guinea pig lung perfusion. Ephedrine was used as the control drug. The drugs thus tested were U-0394 (benzyl alcohol, α-[2-(diethylamino)]-1-phenoxyethyl hydrochloride), U-0910 (propiophenone, 3-dimethylamino 2-p-propoxyphenoxy,-hydrochloride), U-1614 (benzamide, N-[2 diethylaminoethyl]-2,4,6-trimethyl), U-7236 (diphenyl-ethylamine, 0,0′,dimethoxy-N,a,á,-trimethylhydrochloride ethenolate), and McN-A-29-11 (β-diethylaminoethyl 2,3,5,6, tetra methyl benzoate). Aqueous solutions of these drugs were used for experiment. Acetyl choline and histamine were used to induce contraction of tracheal musculature of the dogs and the dose of ephedrine required to reduce by 50% the contraction produced by acetyl choline was taken as unity.

In histamine-induced spasm, U-0394 and U-0910 brought about 50% reduction in a dilution of 1:10,000 but they were ineffective in a dilution of 1:100,000. The other three drugs were unable to counteract the spasm. Ephedrine antagonized the response in a dilution of 1:10,000 only. McN-A-29-11 was as potent as U-0394 and U-0910 in antagonizing the bronchospastic effect of acetyl choline on tracheal muscle but showed no activity in histamine-induced bronchospasm in the same dilutions on tracheal muscle and in guinea pig lung perfusions. U-1614 and U-7236 have a weak bronchodilator effect. Thus, of the five compounds studied, U-0394 and U-0910 were found to be more potent bronchodilators than ephedrine.

Urinary Excretion of 17-Hydroxycorticosteroids.—The normal levels of urinary 17-hydroxycorticosteroid excretion had not been reported for Indians until Patwardhan and Talavdekar (*Indian Journal of Medical Sciences,* vol. 13, June, 1959) did so. The mean values of 24-hour 17-hydroxycorticosteroid excretion as Porter-Silber chromogens were 7.02 mg. for men (range 3.8 to 11.4) and 5.3 mg. for women (range of 1.8 to 8.0). The mean 17 ketogenic steriod content by the Moxham-Nabarro method for men was 9.4 mg. (range 3.4 to 16.7) and that by the modified Norymbeski's procedure was 5.3 mg. (range 2.6 to 9.1). Thus the 17-ketosteroid values for Indians appeared to be a little low compared to those reported for normal American and British subjects.

Enteric Oxygen for Ascariasis.—D. D. Vora and co-workers (*Indian Journal of Medical Sciences,* vol. 13, June, 1959) studied the concentration of oxygen at the end of one and two hours after introducing oxygen into the intestinal lumen. Mongrel dogs who had been starved for 24 hours were given pentobarbital intraperitoneally. After opening the abdomen through a midline incision the small intestine was found to be completely collapsed and contained no liquids or gases. The intestine was brought out and 300 ml. of oxygen was introduced. About 200 ml. was required to fill the small intestine while the rest passed into the colon. The intestine was then tied just distal to the duodenum and proximal to the ileocecal valve. Blood vessels were not included in these ligatures so that the blood supply to the intestines was maintained.

At the end of one hour 54 to 100 ml. of gas was aspirated from the small intestines, their oxygen concentration varying from 84 to 90%. The concentration of oxygen which is therapeutically effective is above 80%, and this was found to be maintained in the small intestine at the end of one hour, while after two hours it was slightly lower but the quantity was not always sufficient for analysis. The anthelmintic action of oxygen can thus be definitely presumed to be exerted during the first hour after intragastric administration in vivo, but its action during the second hour is not predictable.

Therapeutic Insemination.—C. Kar (*J. A. Med. Women, India* 47:2, [May], 1959) stated that homologous therapeutic insemination may be used in the treatment of infertile couples. The semen is obtained preferably by masturbation, the husband having abstained from sexual intercourse for four or five days prior to the collection. This sample is used within two hours of collection after complete liquefaction has occurred. Insemination is accomplished within two to three days of ovulation and two to three inseminations are made between the 10th and 18th days of the menstrual cycle. If poor motility of the spermatozoa is revealed on examination of the semen, it is collected fractionally in separate test tubes and the first part used for insemination, as this is the part which contains the maximum number of motile sperms. The insemination is usually done with a syringe, but the cervical cap method may also be used.

In a series of 40 women sterile for 4 to 18 years, therapeutic insemination was done and in 19 pregnancy was achieved. In three women a single insemination was enough and in eight pregnancy resulted after two inseminations. Of the 19 pregnancies, 6 ended in full-term deliveries. Two had missed abortions in the fourth and fifth and four in the third and fourth months of pregnancy. The rest were still in different stages of pregnancy when last seen. The husband's semen had moderate oligozoospermia (6 to 20 millions per cubic centimeter) in 5 of these 19 cases. The author stressed the importance of proper technique of carrying out this procedure in order to achieve successful results.

Chlorpromazine for Preeclampsia.—S. Bose (*Journal of Obstetrics and Gynecology of India*, vol. 9, 1959) studied the action of chlorpromazine in 243 patients with preeclampsia and concluded that the drug helps to reduce blood pressure, the effect being more marked in patients with a relatively high blood pressure. Because the fall of pressure is transitory, prolonged and frequent administration is necessary to maintain this action. A few patients may even require increasing doses for control of the blood pressure. With the routine treatment, the maternal mortality was 0.54% and the uncorrected fetal mortality 5.7%. For the diagnosis of preeclampsia, a blood pressure reading of 130/90 mm. Hg associated with edema and/or albuminuria was taken as the criterion.

The patients were divided into three groups. Group 1 (84 patients) received 50 mg. of chlorpromazine and 50 mg. of promethazine intramuscularly every eight hours; group 2 (99 patients) received in addition 100 mg. of meperidine intramuscularly; and group 3 (60 patients) served as controls, receiving such sedatives as morphine, barbiturates, bromides, and magnesium sulfate. All patients were on a salt-restricted diet rich in proteins. Diuretics and hematinics were given if necessary. Severe headache and insomnia were the chief complaints. Ability to sleep improved after therapy, the maximum effect being noticed in group 2. Hangover was minimal in group 1. Of those in groups 1 and 2 severe giddiness was reported by 32%. Nausea and vomiting were easily controlled in these groups but were severe at times in group 3. A generalized burning sensation was sometimes a complaint. This was probably due to a vitamin deficiency. Other symptoms such as edema of the ankles and scanty urine responded equally well in all three groups.

The very first injection led to a fall in blood pressure of 20 to 40 mm. Hg. The systolic pressure showed a greater fall than the diastolic. The average duration of the fall in pressure was 6.8 hours and was most marked in group 2. Only seven patients required other hypotensive drugs for control of blood pressure, which were given in small doses due to a synergistic effect. Sixteen patients developed an abrupt pressure fall of 50 mm. Hg but recovered spontaneously. Chlorpromazine did not increase the urinary output any further. Edema and weight gain also were probably unaffected by the drug, the improvement being due to rest and the administration of diuretics. Albuminuria disappeared more quickly in the first two groups, along with the fall in blood pressure. The drug also did not affect the action of hematinics. None of the patients developed jaundice. The total serum protein level was unaltered except in one patient in whom the albumin/globulin ratio showed a change without any liver damage. Only one patient had increased blood urea. Vasospasm of the retinal vessels was most marked in group 3, but it was relieved by the therapy in the first two groups. Sixteen patients gave a history of previous toxemia.

Of those in the first two groups 18% and of those in the third group 25% required induction of labor. Chlorpromazine did not cause prolongation of labor, and the forceps delivery rate was 5% less than in the control group. True eclampsia developed in three primiparas, and accidental hemorrhage occurred in two patients. One patient in the control group developed cardiac failure. Maternal mortality was zero. The total fetal mortality was 4.5%. There was an increased number of premature babies. Fetal loss was greatest in the control group. The rate of occurrence of neonatal asphyxia did not vary in the three groups. Eight patients in group 3 who did not respond to routine treatment did well with chlorpromazine and meperidine. Pulmonary complications were generally absent.

Late Complications of Tuberculous Meningitis.—Nazarova and Mareeva-Khandricova (*Indian Journal of Child Health*, vol. 8, June, 1959) described a neurological complication after tuberculous meningitis that does not respond to specific or nonspecific treatment. A constant symptom of the disease is rigidity of the spinal column, often throughout its entire length but most marked in the lower thoracic and lumbosacral regions. Bending of the trunk backward or forward is limited and may even be impossible. Patients complain of pain in the back, legs, and popliteal space, which is aggravated by coughing and exertion. Scoliosis may be present while the normal lumbar lordosis is replaced by kyphosis. There is tenderness over the spine on percussion. X-ray shows widening of the spinal canal in the lumbosacral regions, usually involving three or four vertebrae. Osteoporosis may be present. All show evidence of strain of the long muscles of the back. Root pain due to involvement of the arachnoid membrane and nerve roots in the lumbar region and radiating to one or both lower extremities is another constant finding. Deformities at the knee and hip joints due to faulty posture or severe contractures may develop. Kernig's sign is positive, and there is neck rigidity. The knee and ankle jerks and abdominal reflexes are absent or sluggish, usually on one side. Wasting of gluteal and calf muscles may be present.

Sensory changes are few. Some patients have retention of urine. The gait is characteristic; when the whole spinal column is rigid, the trunk and pelvis sway around the vertical axis of the patient, the legs are bent, and the patient may walk on his toes. Examination of cerebrospinal fluid reveals absolute and relative protein-cell dissociation, xanthochromia, and evidence of partial or complete block. Patients complain of sudden acute pain radiating to the legs, the perineum, or the bladder during lumbar puncture. The puncture may prove dry, which happened in two patients. Four of 11 patients studied had a high protein content and an increased cell count. Tubercle bacilli were demonstrated in only one patient and another had cholesterol crystals in the spinal fluid. Most of the patients were undernourished, with marked anorexia.

All 13 children had been treated for 6 to 12 months with streptomycin for tuberculous meningitis. The signs and symptoms were due to the development of cholesteatomas in the subarachnoid space involving the nerve roots. In 11 patients these growths were removed surgically. The root pain which was the initial symptom occurred one to six years after the original attack of tuberculous meningitis, when the patients were otherwise perfectly healthy. A diagnosis was tentatively made of spondylitis or arachnoiditis after tuberculous meningitis; they received specific and nonspecific treatment, after which the root pain subsided, but other symptoms persisted and gradually progressed, requiring operation. Laminectomy under general anesthesia was performed and the vertebral arches of L2 to L4 or L2 to L5 were resected. These arches were usually more spongy in texture than normal. The thick and congested arachnoid showed no pulsations on exposure. The cholesteatomas were seen on moving the nerve roots aside as pearly, silky growths with an almost smooth surface, round or oval in shape, and enclosed in a compact vascular capsule. In one patient the growth was single but in the rest 2 to 11 growths were found. No fresh tubercles were seen on the arachnoid. Relief or complete disappearance of symptoms followed removal of these tumors. The postoperative course was uneventful. Specific antituberculosis treatment was given for a month after the operation. Most patients recovered completely. Morphologically these tumors resembled congenital epidermoid cysts.

Treatment of Eclampsia.—M. K. K. Menon (*Journal of Obstetrics and Gynecology of India*, vol. 9, June, 1959) treated 1,151 patients who had eclampsia with various sedatives from 1938 to 1950 with disappointing results, the maternal mortality being about 15.1%. Sodium thiopental was used in 1951 and the recurrence rate of the convulsions was reduced slightly, but the maternal mortality remained high. Antepartum eclampsia resulted in the highest mortality, 17% compared with 6.5% in intrapartum and 9.3% in postpartum eclampsia. The longer the interval between the onset of convulsions and delivery, the greater the death rate. In selected patients with antepartum eclampsia, cesarean section reduced the maternal mortality. The author then gave phenothiazine derivatives to a series of 402 patients. The treatment consisted of 25 mg. of chlorpromazine and 100 mg. of meperidine given intravenously in 20 ml. of 5% dextrose solution, on admission to the hospital; 50 mg. of chlorpromazine and 50 mg. of diethazine were given intramuscularly; an intravenous drip of 20% dextrose solution containing 200 mg. of meperidine was then started and allowed to run in slowly, the rate depending on the response. The intramuscular injections of 50 mg. of chlorpromazine and 50 mg. of diethazine were given alternately every 4 hours for 48 hours.

If convulsions were uncontrolled in 8 to 10 hours, and the patient was not in labor, cesarean section was performed under local anesthesia. If labor had commenced, the membranes were artificially ruptured and delivery was assisted by outlet forceps. With this treatment, the maternal mortality was reduced to 2.2%, the lowest ever obtained by the author. Twelve cesarean sections were done in this series and no mother was lost because of the operation. In this series, 60% showed a satisfactory drop in blood pressure and 95% had a good urinary output. The recurrence rate of convulsions was 15% and pulmonary edema was seen in only five patients. Hyperpyrexia occurred in only three patients while it had occurred as the terminal event in 25.3% of patients treated by earlier methods. Posteclamptic psychosis was rare and shock was absent even with cesarean deliveries. The maternal mortality in patients with severe eclampsia was 2.7% in this series and the perinatal infant mortality was 32.1%. The author believed that this therapy was reasonably effective in controlling convulsions.

In another study in the same issue N. S. Devi found that chlorpromazine was useful in warding off imminent eclamptic convulsions. In this series maternal mortality was nil and fetal mortality was 13.6%.

Toxemias of Pregnancy.—O. Francis (*Journal of Obstetrics and Gynecology of India*, vol. 9, June, 1959) studied 200 consecutive patients with toxemias of pregnancy in order to correlate biochemical and ophthalmoscopic findings with the clinical data; 172 had preeclampsia, 14 had eclampsia, and 14 had essential hypertension. The levels of serum protein and serum albumin were lower among the toxemic patients than in those with normal pregnancy. The fall in these values was more marked in preeclampsia than in eclampsia, and greater in the severe cases of preeclampsia than in the milder ones. The blood uric acid level was raised in preeclampsia and eclampsia and this finding served to differentiate these patients from those with hypertension. This level was reduced in patients who responded to medical treatment. There was no relation, however, between the level of blood uric acid and the development of convulsions. In patients with hypertension both blood urea and uric acid remained within normal levels and the urea/uric acid ratio was high while this ratio was lowered in those with preeclampsia and eclampsia. This served as another differentiating factor. The blood uric acid level was less in those with eclampsia than in those with severe preeclampsia. For funduscopy, the patients were divided into two groups, those with a blood pressure level below and those with a blood pressure level above 160/100 mm. Hg.

A series of 100 patients (37 with mild and 63 with severe hypertension) was studied. Of those with mild hypertension 23 patients and of the other group 25 patients had no changes in the eyegrounds. Of the 10 eclamptics included in this study, 4 had no eye changes. Of 32 patients with mild preeclampsia, 24 and of 35 with severe preeclampsia 20 showed no eye changes. Of 23 patients with hypertension, 18 showed eyeground changes. Eyeground changes and retinitis were seen in patients with severe toxemia as revealed by high blood pressure, severe albuminuria, edema, and the need for termination of pregnancy. The series included 11 patients with retinitis showing hemorrhage and exudates, 2 in the mild group and 9 in the severe group. These cleared under medical treatment in nine patients (two mild and seven severe) and in the remaining two, pregnancy was terminated.

Urinary and Blood Chemistry and Gestoses.—Purandare and Agashe (*Journal of Obstetrics and Gynecology of India*, vol. 9, June, 1959) stated that the excretion of all the amino acids was affected during pregnancy but all others except histidine showed minor changes which were not significant statistically. Histidine is not necessary for maintenance of nitrogen equilibrium but its presence is essential for body growth. It increases in amount in the presence of an actively growing fetus and the weight of the newborn infant varies according to the amount available in the mother's blood. Estimations of urinary histidine showed that in nonpregnant women it varied up to 150 mg. in 24 hours while in normal pregnancy it ranged from 300 to 600 mg. The presence of a dead fetus and toxemia adversely affected this test. Urinary histidine occurred in a free and a bound form. The authors found that the amounts of free histidine did not vary markedly in normal pregnancy and toxemia, although the values in toxemia were slightly reduced. The test for free histidine became completely negative within 10 days of expulsion of the placenta, while its presence depended on the existence of a functioning placenta in the body. The amount of total histidine was reduced as the severity of a toxemia increased.

Blood urea levels in normal pregnancy showed a slight tendency to decrease as pregnancy advanced but in toxemia it steadily continued to increase. The blood urea figures gradually reached normal levels within 10 days of delivery in all patients, showing a progressive rise to normal levels during normal pregnancy and a progressive fall even below the normal figures in toxemic patients. The blood uric acid level showed a progressive rise from 2.6 to 3.1 mg. per 100 ml. in normal pregnancy from the fourth to the ninth month. The postnatal figures did not vary much in normal and toxemic patients and readings obtained in patients whose pregnancy was complicated by anemia, cardiac conditions, or toxemia also did not show significant variations from those with normal pregnancy. The urea clearance showed a progressive decrease with a sudden improvement in the seventh month both in those with normal and those with complicated pregnancy. The diminution in urea clearance was marked as the severity of toxemia increased toward term. The values reached normal within 10 days after normal delivery.

In patients with mild toxemia, a sudden improvement was seen within the first 24 hours of delivery which might again have dropped very low and then started to rise gradually till the normal level was reached within 10 days. The improvement was not so marked in those with severe toxemia but the values gradually returned to normal within 10 days. Values of blood urea varied inversely with the urea clearance. Study of histidine excretion showed an increase in the free histidine in urine in normal pregnancy from traces in the fourth month to about 300 mg. in the seventh month, when a sudden peak was noted. In patients with mild toxemia, the level decreased as pregnancy advanced. No correlation was noted between urea clearance and histidine excretion. A progressive fall was seen in the postpartum period in patients with normal pregnancy, approaching zero by the seventh day, and in those with mild and severe toxemia it was absent within the first 24 hours after delivery.

Estimations of plasma proteins by paper electrophoresis showed a tendency toward a fall in total proteins and albumin in normal and toxemic patients. Depending on the severity of the condition, the drop was greater the higher the initial level in the first half of pregnancy. An increase in globulin occurred which varied inversely with the initial levels. There was a definite relation between the level of serum albumin and the presence of toxemic symptoms. A very low serum albumin level in early pregnancy indicated a bad prognosis. An increased production of total globulins was noted in patients with normal pregnancy and preeclampsia, but an actual fall in globulin level occurred in those with eclampsia. In spite of the fall in total globulin, the gamma globulin showed a rise in patients with eclampsia. The alpha-1, alpha-2, and beta globulin levels increased in patients with normal pregnancy and preeclampsia but these showed no rise in those with eclampsia although fibrinogen levels were increased significantly.

A rise in fibrinogen was also seen in patients with normal pregnancy and preeclampsia but this was not so marked as in those with eclampsia. In patients with concealed type of accidental hemorrhage, hypofibrinogenemia or actual afibrinogenemia was seen and in those who had placenta praevia with bleeding, no such fall was observed. Patients with essential hypertension complicating pregnancy did not show a rise in fibrinogen.

Vaginal Cytology.—T. S. Cheema (*Journal of Obstetrics and Gynecology of India*, vol. 9, June, 1959) made vaginal smears of 101 patients with erosions, polyps, and ulcers of the cervix. Smear examination was followed by biopsy or histological examination of the cervix removed at operation. A minimum of three smears were studied before a report of negative findings was made. Sections of the cervix were available for examination in 100 of these patients. In 42 patients the sections showed a definite carcinoma. The vaginal smear was frankly positive for cancer in 40 patients. This included one with papilliferous adenocarcinoma of the ovary and one with primary carcinoma of the vagina. Four patients had negative smears repeatedly, though biopsy definitely showed a carcinoma. Of 57 patients with histological findings negative for malignancy, 3 showed atypical smears. Two had Trichomonas infection locally and one had a signet-ring type of cell, the biopsy report being acute inflammation of the cervix. There were no false-positive smears in this series. The smears may have helped in prognosis as happened in two patients whose malignant cells were cast off in sheets while in one numerous mitotic figures were present. Both patients had a rapid downhill course. The author concluded that a frankly positive vaginal smear with a clinical diagnosis of malignancy calls for immediate treatment for carcinoma rather than waiting for a biopsy report.

Hydralazine and Reserpine for Preeclampsia.—M. K. K. Menon (*Journal of Obstetrics and Gynecology of India*, vol. 9, June, 1959) stated that an ideal hypotensive drug for preeclampsia should lower the blood pressure and maintain it at normotensive levels throughout pregnancy without causing any adverse effects on either the mother or the fetus. With this view, hydralazine was given to 110 and reserpine to 183 patients with preeclampsia. Cases of hypertension complicating pregnancy with or without superimposed preeclampsia were excluded from study. The patients were divided into groups with mild (group 1) and severe (group 2) manifestations (hypertension, edema, albuminuria, headache, visual disturbances, and restlessness). All were hospitalized and treated with bed rest, sedation, salt-poor diet, and acetazolamide for 48 hours after which hydralazine and reserpine but no sedatives were given. Patients in group 1 received 50 mg. of hydralazine orally at first. The dose was increased by 50 mg. daily till the blood pressure became normal. This dose was maintained for 48 hours and then gradually reduced by 50 mg. daily.

Patients in group 2 did not respond satisfactorily to hydralazine by mouth and were therefore given the drug intravenously in an initial dose of 20 mg. Injections were repeated depending on the response but more than three doses a day were not given. Reserpine was given in doses of 1 mg. three to six times a day by mouth to patients in group 1. Those in group 2 were given the drug parenterally. The average dose for these patients was 2.5 to 5 mg. every 4 to 6 hours but not more than 20 mg. was given in 24 hours. Other patients with preeclampsia treated without these drugs served as controls. With oral doses of hydralazine in patients in group 1, the response was good in 30% and with reserpine the response was good in 60.4%. The fetal salvage rate or the rate of induction of labor was not reduced by oral doses of hydralazine in these patients. It took an average of 8.2 days to get the normotensive effect while in the control group this interval was 6.2 days. The drop in blood pressure was slow and gradual. No untoward symptoms were observed.

With reserpine also there was no marked improvement in the premature birth rate or the perinatal death rate. Of 58 patients receiving the drug orally, only one developed eclampsia while in the control group 4 mothers died. The average time required to reach the normotensive level with reserpine was 5.3 days compared with 6.2 days in the control group. Seventy patients in group 2 received hydralazine. Response to oral therapy was unsatisfactory. When the drug was given parenterally, the blood pressure started falling steeply within about 10 minutes of injection. The maximum drop was 55 mm. Hg systolic and 30 mm. Hg diastolic; 75% came down to normotensive levels within three hours of injection. The hypotensive effect lasted 3 to 26 hours. The urinary output was adequate in 96%. The drug on the whole was useful in controlling blood pressure in these patients and both the prematurity rate and the perinatal death rate were reduced (16.6% and 13.3%, respectively, compared with 21.3% and 19.3% in the control group). One mother in this group developed eclampsia. The hypotensive effect with hydralazine given intravenously was almost immediate, marked, dependable, and lasted the longest of all the hypotensive therapies given. Side-effects were negligible. Tachycardia was constantly seen, 3 patients complained of palpitation, 10 had hot flushes, and 3 had headache and vomiting.

With reserpine, no appreciable fall occurred for almost 45 minutes after the injection. The average time required to reach the normotensive level was 4.6 hours, the maximum fall observed being 50 mm. Hg systolic and 30 mm. Hg diastolic. The urinary output was adequate in 90%. The premature birth rate and the perinatal death rate were not improved by reserpine. Two patients developed eclampsia. The chief side-effects were drowsiness, nasal congestion, gastrointestinal upset, and urticaria. Fifty patients with preeclampsia in labor were given reserpine intravenously. They had received no hypotensive drugs prior to labor. In only 14 was an appreciable fall noted; 21 did not respond at all. It took about 45 minutes for the blood pressure to drop and the drop was sustained for 1.8 hours; 35 needed a second injection after 4 hours; and 2 developed intrapartum eclampsia in spite of the reserpine.

Hypotensive Drugs and Pregnancy.—O. J. Shah (*Journal of Obstetrics and Gynecology of India*, vol. 9, June, 1959) stated that the intravenous administration of protoveratrine causes a rapid fall in blood pressure in hypertensive pregnant women which lasts for two or three hours and is at times associated with severe vomiting and collapse. Intravenous administration of reserpine, on the other hand, causes a relatively smaller reduction of blood pressure which occurs after a latent period of about 2 hours and lasts about 12 hours. A preparation causing a rapid and moderate fall of blood pressure lasting for some time and with no side-effects should be desirable in pregnant women with hypertension. The author gave a preparation parenterally which combined optimal doses of protoveratrine and Rauwolfia alkaloids, for optimal action with elimination of undesirable side-effects. This was given intramuscularly and the dose was repeated after four hours if no fall in blood pressure was recorded by that time. A maintenance dose was given when the pressure started rising after 12 to 18 hours. Blood pressure readings were taken every half hour for the first 4 hours, then every 3 hours for 12 hours and later three times a day.

A series of 24 pregnant women with hypertension, 17 with preeclampsia, and 7 with hypertension complicating pregnancy were thus treated. Two patients were given intramuscular injections of 50% magnesium sulfate solution to control severe convulsions. No other drugs or sedatives were used. Five patients with preeclampsia did not respond at all to the hypotensive injection. The remaining patients responded satisfactorily, the systolic pressure showing a fall of 5 to 65 mm. Hg and the diastolic pressure showing a fall of 15 to 40 mm. Hg after the first injection. The action appeared within about one hour and the peak was reached within four hours. The effect lasted for 12 hours and in one patient the reduction was maintained for five days. Clinical improvement ran parallel with the blood pressure response. The fetal mortality was, however, unaffected. Side-effects such as transient giddiness or vomiting were minimal.

SWEDEN

Neurological Complications After Myelography.—Since no neurological side-effects of myelography with 20% methiodal had been reported, Lennart Söderberg and co-workers (*Acta orthop. scandinav.* 28:220-223, 1959) reported that in the last six years myelography with this water-soluble contrast medium was performed about 760 times at the Malmö General Hospital. There were serious complications in three patients. After premedication with 0.5 ml. of morphine-scopolamine the patient was placed on the side to be examined, the head of the examination table was raised, and 1 ml. of ephedrine was given subcutaneously. Spinal anesthesia was induced, after which 10 ml. of methiodal was slowly injected. Lateral, oblique, and posteroanterior films were taken with the patient in the lateral, semiprone, and prone positions. After the examination the patient was kept in bed for eight hours with the head of the bed raised. The complications occurred in three men, aged 43, 39, and 53 respectively. These complications were obstinate and regressed but slowly. During a follow-up of 6 to 24 months, symptoms of varying severity still persisted. The question arose whether these complications might have been due to the contrast medium as such, to hypersensitivity, to incomplete anesthesia (epidural deposition), or to the spinal anesthetic agent. The authors concluded that since myelography was so valuable in the exact diagnosis of disk protrusion when an operation was indicated and since methiodal was the best contrast medium available for this purpose, that this method was justified despite the slight risk of complications.

Diaphragmatic Mobilization.—Although the need for a space-diminishing procedure after pulmonary resection for tuberculosis has decreased greatly in the last two years, many patients are still seen for whom a space-diminishing operation is indicated. V. O. Björk (*Acta chir. scandinav.* 117:18-26, 1959) believes such an operation is indicated when (1) more than one lobe is resected, (2) there is bilateral widespread tuberculous infiltration, (3) resection is performed for tuberculous empyema, and (4) resection with decortication is performed on a patient who previously had a pneumothorax and in whom the remaining pulmonary tissue is too fibrotic to fill the space. A pilot study was made with various types of resection in 17 cases, and none of the patients died. No special complications occurred. Diaphragmatic mobilization and resuturing at a higher level gave results described as follows: In two patients in whom this operation was performed in conjunction with left pneumonectomy after a preliminary apical four-rib or five-rib thoracoplasty, an excellent result was obtained. The mediastinal hernia from the right side was small. Although the diaphragmatic operation is preferred in such patients to a total thoracoplasty, the same result would probably be obtainable by cutting the phrenic nerve, which is a much simpler procedure.

In a patient with the diaphragmatic operation and right upper lobectomy 32% of the total oxygen uptake postoperatively occurred on the right side. This value is within the range of 27 to 49% oxygen uptake found in a group of 15 patients reported on two years ago who had right upper lobectomy and osteoplastic roof thoracoplasty. The ipsilateral ventilation likewise was 32%, which, however, was less than that found after osteoplastic thoracoplasty (37 to 69%, mean 50%). After resection of the right upper and middle lobes and diaphragmatoplasty the dislocated right lower lobe did not function. The same observation was made after resection of the left upper lobe plus the superior segment of the left lower lobe. In both of these patients who had complete loss of function despite a mobile diaphragm, no oxygen uptake or ventilation could be demonstrated on the treated side and there were clinical signs of stenotic breathing. Bronchography showed that when the remaining basal segments were dislocated to the apex of the thorax by the new position of the diaphragm, the bronchus was distorted and kinked in such a way as to make ventilation impossible.

In a patient with right lower and middle lobe resection and diaphragmatoplasty the ipsilateral function (27% oxygen uptake) was as good as after osteoplastic thoracoplasty (24 to 25%) or conventional upper thoracoplasty (23 to 26%). The ventilation (33%) was also as good as after other space-diminishing procedures (34 to 39%). After resection of the apicoposterior and anterior segments of the left upper lobe and diaphragmatoplasty, the ipsilateral oxygen uptake (25 to 29%) was similar to that found after this resection plus osteoplastic thoracoplasty (27%). The ventilation of 11 to 18% after the diaphragmatic procedure, however, was significantly lower than the 27% registered after left-sided osteoplastic thoracoplasty. The cosmetic result was excellent. Of 17 patients 16 had no postoperative abdominal symptoms and one complained of eructation.

Björk concluded that the diaphragmatic operation could be used only after resection of the basal portions of the lung, then the remaining function would be as good as after other procedures, and, while osteoplastic thoracoplasty was the preferred technique to diminish the thoracic cavity, the diaphragmatic operation was not recommended.

Coagulation and Extracorporeal Circulation.—Nilsson and Swedberg (*Acta chir. scandinav.* 117:47-54, 1959) studied the coagulation in 17 patients subjected to cardiac operations with extracorporeal circulation using a bubble pump-oxygenator. This observation was prompted by experiments on dogs in which extracorporeal circulation was often found to be accompanied by diffuse fatal hemorrhages, and coagulation studies from some of these animals showed that extracorporeal circulation was followed by fibrinolysis. Plasmin activity in the blood was regularly increased during the operation. In some of the patients plasmin activity was increased even before perfusion. Independent of the presence or absence of plasmin activity before perfusion, the activity regularly increased during perfusion. The fibrinogen concentration decreased from an average of 0.29% before to 0.13% after perfusion. At the same time a marked decrease was noted in the antihemophilic globulin (AHG) and factor V values. The plasminogen and proactivator content decreased. The drop in the prothrombin and hemophilia B factor was only moderate during perfusion. The thrombocyte count regularly decreased but not below 98,000 per cubic millimeter.

The fibrinolysis observed in these patients and the subsequent drop in fibrinogen might be regarded as moderate. A contributory cause might be the activation of the fibrinolytic system being limited to such a short period. It should be emphasized that fibrinolytic activity alone does not necessarily cause hemorrhage. On the other hand fibrinolytic activity and the hypofibrinogenemia in combination with such other coagulation defects as thrombocytopenia, AHG-deficiency, and factor V deficiency, may be contributory factors in the causation of bleeding. The fibrinolysis was therefore regarded as sufficient to indicate fibrinogen therapy.

All of these patients received fibrinogen in varying amounts (2 to 15 Gm.) after the perfusion. There was no evidence of bleeding except in one patient who incurred a cerebral injury during the operation and at the same time developed strikingly high plasmin activity. After administration of 15 Gm. of fibrinogen the hemorrhage decreased. As slight fibrinolytic activity occurs during most surgical operations, a study was made of the blood for changes in coagulability during 14 operations on the lung and heart for comparison. Increased plasmin activity was demonstrable in the blood during these operations, but the increase was less than in those for whom extracorporeal circulation was used. The decrease in fibrinogen, like that in the other coagulation factors was also much less than that noted during extracorporeal circulation.

The authors concluded that fibrinolysis during extracorporeal circulation was most pronounced in those patients with the most pronounced metabolic disorders (pH-decrease, CO_2-increase, lactic acid increase, and potassium decrease) and in whom the blood pressure could not be maintained. The cause of fibrinolysis during extracorporeal circulation is not properly understood, but it may be due to such contributing factors as released activators from injured tissues in the same way as in other major operations, and the metabolic changes are also probably significant.

Plasma-Heparin Concentration.—Extracorporeal circulation is made possible by rendering the blood incoagulable with the aid of heparin. As a rule the patient is given 1.5 to 3 mg. of heparin per kilogram of body weight and to the blood that is used for filling the heart-lung machine 15 to 30 mg. per 500 ml. of donor blood is added. As it seemed from earlier experiments that at the lower heparin dosage there was some initiation of coagulation and it was thought by Åke Senning (*Acta chir. scandinav.* 117:55-59, 1959) that this might give rise to disturbances of coagulation, plasma-heparin determinations were made. Each of 13 patients was given citrated blood before and after extracorporeal circulation. The patients received 4 mg. of heparin per kilogram of body weight just before the perfusion cannulas were inserted. The donor blood which was used to fill the heart-lung machine contained 13 mg. of heparin in 50 ml. of 5% dextrose solution per 450 ml. of blood. When perfusion had been terminated and the heart had taken over the circulation, 15 mg. per millimeter of protamine chloride was injected in two or three divided doses to give a coagulation time of seven minutes or less.

After perfusion 1 Gm. of fibrinogen was also given. After administration of 4 mg. of heparin per kilogram of body weight the concentration of heparin in the plasma ranged from 7.6 to 4.6 I. U. per milliliter. During the preparatory phase of the operation these readings fell by a mean of 1.8 I. U. per milliliter per half hour; 15 mg. of heparin in 50 ml. of 5% dextrose solution added per 450 ml. of donor blood produced an average plasma-heparin concentration of 4.5 I. U. per millimeter. During extracorporeal circulation the plasma-heparin readings fell by a mean of 0.6 I. U. per milliliter per hour. The author concluded that 4 mg. of heparin per kilogram of body weight was a suitable dose; 15 mg. of heparin in 50 ml. of 5% dextrose solution seemed to yield somewhat too low a plasma-heparin concentration. If the preparatory phase before by-pass was long or if perfusion was protracted, additional heparin should be given to reduce the risk that coagulation would be initiated by heparin elimination. Heparin rebound did not seem to occur in the period immediately after neutralization of heparin with protamine.

Tetralogy of Fallot.—Among persons with congenital anomalies consisting of pulmonic stenosis coexistent with ventricular septal defect, all grades may be found, from slight stenosis with large left-right shunt and possibly elevated pulmonary arterial pressure to severe stenosis producing right-left shunt with a small pulmonary arterial flow and low pressure. It would further seem that during the years of growth the pattern may alter so that left-right shunt may decrease in size and gradually be transformed into a right-left shunt, at first during exertion and later at rest. Åke Senning (*Acta chir. scandinav.* 117:73-81, 1959) reported a series of 27 patients with ventricular septal defect, pulmonic stenosis, and right-left shunt who were subjected to open correction of the defects, using extracorporeal circulation. Five had already undergone shunting operations and two had had the Brock operation.

Among the 20 in whom the open-heart operation was the primary measure there were four deaths. In all of the fatal cases there was an anomalous coronary artery crossing the infundibulum in the right ventricle. One of the patients who underwent reoperation after palliative anastomosis died of septicemia. The mortality in patients primarily treated with open-heart correction is somewhat higher than the primary mortality in shunting operations, but it may be expected to fall as experience is gained. In the present series anomalous coronary arteries traversing the infundibular stenosis prevented adequate enlargement of the outflow tract in three patients and these patients died. A systolic murmur was still audible in most of the survivors when last seen. Catheterization, however, revealed no persistent defects of hemodynamic significance. The author concluded that open operation was appropriate for Fallot's tetralogy. Patients who had previously undergone palliative shunting operations should also be considered for an open operation.

Pulmonary Stenosis.—During 1,000 consecutive heart catheterizations performed at the Pediatric Clinic of Karolinska Hospital 72 patients were found to have pulmonary stenosis. Of these, 28 patients were operated on. In selecting patients for operation, a right ventricular systolic pressure of 75 mm. Hg was generally considered the boundary line separating the mild from the moderately severe types of stenosis. Patients with levels above this showed marked clinical impairment of physical capacity, marked electrocardiographic evidence of right ventricular hypertrophy and strain, or both. Danae Ikkos (*Acta chir. scandinav.* 117:82-88, 1959) reported that three types of operations were used; 19 patients were operated on by Brock's transventricular approach, 7 by the transpulmonary artery method, and 2 were operated on for relief of an isolated infundibular stenosis by infundibulectomy, one by the transventricular, and one by the open approach.

Two of the 28 died in connection with the operation. One of these had severe decompensation and the other had an associated large atrial septal defect, undiagnosed before the operation. Of the remaining 26 patients 25 were reexamined postoperatively. Cardiac catheterization was performed on all 25 and angiocardiography on 10. All showed a postoperative decrease in the systolic pressure of the right ventricle (RVP). The typical stenotic murmur which preoperatively showed a peak in either mid or late systole changed in both position and character. In electrocardiography a statistically significant reduction in the degree of axis deviation was observed postoperatively, with most returning to normal values. Correlative signs of right ventricular hypertrophy also showed regression toward normal values after operation. Although the heart volume was in most patients within the normal limits preoperatively, the operation resulted in a decrease of the heart volume in these. This decrease was more pronounced in patients with a cardiac enlargement preoperatively.

The author concluded that it was of interest that when the data reported by the different operation groups were taken together there was a highly significant correlation between the preoperative and postoperative systolic RVP. This finding showed that the selection of the time for operation might be of more importance than the operative technique used and that ideal results might not be uniformly obtainable by any method in patients with severe and prolonged right ventricular hypertension.

Open Versus Closed Treatment of Pulmonary Stenosis.—V. O. Björk (*Acta chir. scandinav.* 117:97-101, 1959) reported a series of 21 patients operated on for relief of pulmonary stenosis. These patients had an intact ventricular septum. Those with a RVP of 80 mm. Hg or more were accepted for operation. The highest RVP encountered was 170 mm. Hg in a 3½-year-old child. The average systolic pressure in the right ventricle was 116 mm. Hg. Seven patients were operated on with the transventricular (Brock) method, 4 with a closed transarterial (Söndergaard) method, and 10 with an open transarterial (Björk) method using inflow occlusion in normothermia. It was found that the Söndergaard method was unsuitable for small children. The author had to improvise the third method and found it to be such an easy technique that he has used it in preference to the others ever since. There were no deaths in the whole series.

Björk considered open valvotomy in normothermia technically easier to perform in all age groups than the other operations. The anatomic result was far superior. The time limit allowed is adequate if no unnecessary procedures are undertaken. Perfusion of oxygenated blood is better omitted as being unnecessary. No clamps should be applied to the aorta or peripherally to the pulmonary artery. An interval of 15 seconds should be allowed after the inflow occlusion before the clamp over the incision is removed. The field is then dry and no time is lost in suctioning blood. When the clamp is reapplied over the incision after the valvotomy, it is better to fill the right ventricle and pulmonary artery with dextrose solution than to release the vena cava. This was done once but the forceful ejection of blood from the hypertrophied right ventricle made it impossible to place the clamp over the incision and another inflow occlusion had to be made for this purpose. This was the case with the longest occlusion, i. e., 2 minutes and 30 seconds, where 30 seconds were lost for the second inflow occlusion and reapplication of the clamp over the incision. When this technique is followed in detail its performance requires no more than two minutes. Hence hypothermia is unnecessary. After the inflow occlusion is made it takes about 20 minutes before the systemic blood pressure reaches zero. Once the caval occlusion is released normal blood pressure is reached within 5 seconds.

Constrictive Pericarditis.—Different types of acute pericarditis have long been regarded as precursors of the constrictive form. Tuberculous pericarditis was formerly associated with a mortality approaching 90%. Purulent pericarditis was almost always fatal unless drained surgically. The rheumatic forms were only part of a disease in which the myocardial and endocarditic processes were of foremost importance. Another question was whether or not rheumatic pericarditis led to the chronic constrictive form. Lennart Johansson (*Acta chir. scandinav.* 117:104-107, 1959) reported on the experience gained from more than 50 patients with constrictive pericarditis of whom 50 had hitherto been treated surgically. The postoperative mortality in the series was six, and one late death was due to progressive pulmonary tuberculosis. The first 38 patients to be treated were followed up as completely as possible. All of the deaths occurred in this group, leaving 31 patients for long term follow-up. Of these, 27 had resumed occupations varying in strenuousness from tree-felling to domestic tasks. Cardiac catheterization of these 27 patients showed conditions to be normal in 22, but further examination including pulmonary function, roentgenograms, and electrocardiography left only 3 patients with fully normal findings.

The author concluded that the cause of chronic constrictive pericarditis was usually infectious. Tuberculosis predominated among the infections leading to the condition. The portion of the heart of greatest importance from the standpoint of hemodynamics was best approached by a left thoracotomy. The wish to free the left ventricle first was founded on angiographic observation that the left ventricle was usually of normal or less than normal size while the right was enlarged. Consequently, the inability of the left ventricle to receive a sufficient amount of blood was one of the major factors, and it followed that this portion of the heart should be freed first. The decortication of the right ventricle should be accomplished next.

Pericardiectomy for Constrictive Pericarditis.—Acute pericarditis leads in most patients to adhesion of the pericardial layers which produces no clinical symptoms and is usually detected only at autopsy, but, in a relatively small number of patients, chronic constrictive pericarditis may develop after a widely varying period of latency. This is marked by adhesion and dense fibrous thickening of the pericardial layers which are not infrequently calcified to a hard husk hindering the normal function of the heart. Surgery must then be considered. Arne Malm (*Acta chir. scandinav.* 117:116-123, 1959) reported that pericardiectomy was performed on a series of 15 patients. While tuberculosis is generally held to be the most frequent cause of constrictive pericarditis, evidence of tuberculous causation was present in only three of these patients; in three others the origin was almost certainly rheumatic, and in four the condition was a sequel of acute nonspecific pericarditis. In the largest group comprising the remaining five patients, the etiological factor was wholly unknown.

Attention was drawn to the diagnostic value of cardiac catheterization with its characteristic pressure changes. Angiocardiography elicited nothing of diagnostic value. The aim of surgery should be total pericardiectomy, but the desire for radical measures in the individual patient should be weighed against the dangers of resecting a firmly infiltrating and calcified pericardium from a poorly functioning and thin-walled myocardium. This series included two primary and three late deaths. Of the remaining patients, four were improved, two much improved, and four became subjectively and objectively asymptomatic. Preoperative atrial fibrillation, high-grade hypoproteinemia, and symptoms of long duration were unfavorable prognostic signs from the surgical standpoint. Calcification of the pericardium was found to be of minor importance. The author concluded that a patient with constrictive pericarditis combined with atrial fibrillation and high-grade hypoproteinemia, in whom the symptoms were of several years' duration, was a poor surgical risk. Operations for constrictive pericarditis should be performed early in the course of the disease, before the progressive myocardial atrophy and liver insufficiency become irreversible.

Closed Versus Open Treatment of Septal Defects.—V. O. Björk (*Acta chir. scandinav.* 117:166-173, 1959) reviewed a series of 47 operations for atrial septal defects. The circular suture method was used in 23 patients. There were no deaths in this group. Atrioseptopexy was used on one patient with a high defect and abnormal venous return. It was attempted on another patient but was abandoned, as a circular suture was found to cause less obstruction to the superior vena cava. Open closure with the aid of a heart-lung machine was used on three patients. One of these died from pulmonary complications and another developed sternal osteitis. The perfusion time varied between 9 and 19 minutes. Björk abandoned this method, however, as the results were so much better when closure was performed under hypothermia.

Twenty uncomplicated atrial septal defects of the secondary type were operated on with no deaths by use of open closure with the aid of hypothermia and coronary perfusion of oxygenated blood. One 15-month-old child who had a secondary defect complicated by fibroelastosis of the left ventricle died two days after operation from failure of this ventricle. The advantage of coronary perfusion is twofold: it diminishes the risk of ventricular fibrillation and it prevents air embolism. The circular suture method was found to be the best of the closed methods. Open closure with the aid of hypothermia and coronary perfusion was, however, regarded as the operation of choice for all patients. Complete closure was most easily obtained under direct vision. Anomalous venous return was more conveniently dealt with when the approach was open. Mortality was not increased by the use of hypothermia and an open technique.

PERSONAL EXPERIENCE WITH SOCIALIZED MEDICINE

To the Editor:—Time is the only factor that distinguishes the two systems of socialized medicine, *namely, that system immediately identifiable as* socialized medicine, authorized by legislature, with establishment of public institutions and bringing into effect laws controlling its practice, as is now the case in Great Britain, and the system of disguised socialized medicine, which is supported by legal regulations and masked by a network of seemingly private committees and insurance companies. The administration of the social medical laws is transferred to these organizations, which then possess legal status. For many years I gained experience with the second type of socialized medicine in the Netherlands. This type is far better adapted to delude the medical profession than is identifiable socialized medicine.

About the turn of the century in the Netherlands there existed the so-called physician funds, founded and conducted by private physicians. Guided by humanitarian instincts, they provided medical care to low-income groups for a negligible weekly premium. These private institutions, scattered over the country, did not have any mutual relationship. Gradually they were taken over and incorporated by private insurance companies. Many unsuspecting physicians were pleased, because their administrative burden was removed. Up to the time of the German occupation of the Netherlands, the income from private practice was generally greater than the income paid by the insurance companies. The Nazi regime imposed compulsory socialized medicine in the Netherlands, but in a limited degree. After the liberation the successive socialistic governments maintained all these regulations, gradually increasing their spectrum. At first every employee and his family earning less than 2,500 guilders ($700) a year was compelled to register for medical care. The premium was withheld from the wages, and at the same time a premium paid by the employer was added. The income limit was increased to 3,400 guilders ($900) a year and, step by step, from year to year, the limit of compulsory insurance was raised and is now 6,900 guilders ($1,800). Entire groups of employees, sailors, officials, and the aged were added piecemeal to this insured category, but never at the same time. At present about 95% of the population is compelled to accept socialized medicine by this subtle, indirect mechanism.

Compromise of Quality of Medical Care

Under socialized medicine the unlimited availability of medical care, treatment, and preventive medicine entails overcrowded waiting rooms and waiting lists for nonemergency hospital treatment. There is no time for a skillfully taken history and an adequate examination. Under this system a conscientious physician will attempt to salvage his responsibility by referring serious cases to a specialist. As a result of this situation the aforementioned committees have compelled the physician to refer no more than the average referring rate of the area of their jurisdiction, at the risk of a financial penalty subtracted from his professional insurance income.

The rising cost of drugs and diagnostic procedures requires a continuing increase of premium payments. Another semiofficial committee is appointed to arbitrarily compose a list of drugs which the physician must choose from. This committee also specifies how much of any drug a physician may prescribe. A drug not mentioned in this list cannot ordinarily be prescribed, even if the patient is willing to pay for it. Infringement of this rule is punishable by subtracting the cost of the drug from the physician's income.

Another rule is, if the average cost of prescriptions of a physician is over 10% of the average cost of prescriptions in the area, this excess shall be subtracted from his income. A host of officials and offices are needed to calculate this material. The committees and insurance companies maintain the fiction that every drug deemed necessary by the physician can be prescribed. To preserve the fiction of this system another committee is appointed to evaluate requests for prescriptions of unlisted drugs. Because these committees meet usually once a week, most physicians refrain from the red tape of such detailed written documentation. Every Dutch physician swears before obtaining his license that he will practice medicine to the best of his ability and knowledge. Thus he is in continual conflict with his professional and moral conscience.

Dangers to the Physician

The insufficient time available for each patient leads to the treatment of symptoms only, so a truly serious illness is often recognized too late. To earn a living a physician is forced to treat an excessive number of patients on a quantity rather than a quality basis. A fixed sum is paid quarterly for each patient. Each patient obtains the right of unlimited house and office calls. Because most conditions seen are not serious, there is a tendency to see each complaint as a trivial or temporary ailment. Most Dutch physicians, therefore, believe that they are handicapped in the performance of their duties. Attempts by physicians to limit the number of house and office calls by requiring a small fee for each visit (so-called limiting ticket) have failed, because the rights given to the patient by the law could not be compromised.

Warning to the Medical Profession

I am now practicing in the United States, and I feel it my duty to make known this information on socialized medicine. The insidious, step-by-step, intrusion of socialized medicine into our private practice causes less resistance on our part than the abrupt transition such as that which occurred in England. I am convinced that, if the individual American physician becomes aware of these disguised dangers, he will resist the intrusion of socialized medicine by all available means. The unity shown by Dutch physicians, during the German occupation, against the compulsory Nazi physician's organization proves that even a reckless enemy cannot force his will on a united medical profession. Unfortunately the disunity created among Dutch physicians, particularly among their leaders, concerning the introduction of social medical laws after the liberation, has caused a situation from which one can escape only by emigration. I am grateful to be privileged to practice medicine in America today. I trust, it will not be again a case of "too little and too late."

POSTOPERATIVE SIGN OF SILENT MYOCARDIAL INFARCTION

To the Editor:—The article "Cold Foot—Postoperative Sign of Silent Myocardial Infarction," by Dr. Nathan Frank, in The Journal, July 4, 1959, page 1147, deserves comment. Dr. Frank states: "The purpose of this paper is to describe a syndrome that has not been previously reported." The occurrence of a cold foot postoperatively is not a syndrome, nor is it a sign of anything except possible interference with the circulation to that particular extremity. Dr. Frank mentions the numerous sources of emboli which may cause vascular occlusion in a distal vessel. To these should be added thrombosis in situ and selective vasoconstriction without "organic" cause.

No electrocardiograms were taken preoperatively and no mention is made of serial changes in tracings subsequent to those illustrated. This would be particularly important in case 3, since the tracing illustrated is quite typical of those seen in pulmonary infarction, which the patient soon was proved to have. The tracing in case 2 shows marked T-wave negativity without reciprocity and without Q waves. Such a pattern could be seen in a host of myocardial diseases and extracardiac conditions. Among the latter is severe anemia, which this patient was proved to have a few months prior to surgery (Durham: *Delaware State M. J.* 19:132 [July] 1947). If a recent nontransmural infarction had occurred, a mural thrombus would be unlikely. The electrocardiogram in case 1 does illustrate an anterior wall infarction, but no proof of its recency is offered.

Correlative evidence of acute myocardial infarction by transaminase levels and sedimentation rates is not offered. All the patients are said to have recovered "uneventfully"; yet no mention is made of the fate of the involved leg. Did oscillometric readings and pulses return to the preoperative state? Last, a routine postoperative electrocardiogram in the recovery room is not justified.

Dr. Frank has correctly stressed the importance of watching the legs in the postoperative period and remembering that silent myocardial infarctions do occur at this time, but to associate these occurrences in a new syndrome is unwarranted.

J. Richard Durham, M.D.
623 Delaware Ave.
Wilmington 1, Del.

To the Editor:—I have read the article in The Journal, July 4, 1959, page 1147, by Dr. Nathan Frank, describing the cold foot as a postoperative sign of silent myocardial infarction. This would be an interesting observation if adequately substantiated. However, it is wise to exhibit caution on interpretations of such a positive sign without adequate pathological explanation of its pathogenesis. It would be tragic, indeed, if patients were not given the benefit of embolectomy or other definitive treatment directed at the extremities on the assumption that this could be due in some unexplained way to silent myocardial infarction.

It is difficult to adequately interpret electrocardiograms from small reproductions such as those that accompany this article. However, after close scrutiny, I feel that in case 1 an anteroseptal infarction is certainly apparent, but I do not believe that its age can be determined from this tracing. In case 2 the electrocardiogram appears to show results more consistent with those of myocarditis or pericarditis; I can see no positive evidence of an infarction on this tracing. In case 3, likewise, no good positive evidence of posterior infarction is shown by the electrocardiogram; in fact it is more consistent with an impression of pulmonary infarction. This impression is further substantiated by later clinical and roentgenographic evidence of pulmonary infarction.

I agree that preoperative electrocardiograms are of inestimable importance in evaluating situations of this type, but I do not believe that sufficient evidence has been presented in this paper to permit these observations to be classified as a syndrome.

LEONARD A. KLEINMAN, M.D.

Garfield Heights 25, Ohio.

To the Editor:—In the July 4 issue of THE JOURNAL appears an article by Dr. Nathan Frank which describes a new sign of silent myocardial infarction, namely, the postoperatively cold foot. Dr. Frank should be commended for his keen clinical observation and his interesting presentation of the cases. However, in studying the tracings presented in his article, I noticed the presence of negative T waves but the complete absence of the corresponding Q waves or S-T segment changes which are necessary in conservative interpretation of acute myocardial infarctions. T-wave changes only were well documented in different clinical conditions, i. e., stress, coronary insufficiency, pericarditis, electrolytic imbalance, severe infections, and even glucose infusion. Since Dr. Frank admits "that the only evidence of myocardial infarction was electrocardiographic," I wonder if any additional electrocardiograms were obtained with further evidence of myocardial infarction.

REACTIONS TO POISON IVY EXTRACT

To the Editor:—Swarts and Rourke (*J.A.M.A.* 170:1409 [July 18] 1959) maintain that the self-administration of Aqua Ivy tablets for prophylaxis of Rhus dermatitis is hazardous. Four members of one family developed cutaneous reactions after one tablet on three alternate days, and another patient developed purpura and joint swelling after a similar dose.

I dissent strongly from the above-mentioned incrimination of Aqua Ivy as the cause of these reactions. Although I believe that this agent is not very helpful in prophylaxis, I am even more certain that it is essentially harmless. In my experience, Aqua Ivy is a weak antigen. None of my patients has complained of untoward effects when the tablets are used in the prescribed way. Lack of side-reactions is the outstanding quality which separates Aqua Ivy from the more potent Rhus allergens that I have studied experimentally (*A.M.A. Arch. Dermat.* 78:47 [July] 1958). Furthermore, large doses of strong Rhus allergens did not produce joint pains and petechiae. Swarts and Rourke cite my article to document their remark that the use of Rhus extracts may damage the kidneys, but my discussion emphasized the very opposite, that there was no good evidence of kidney damage from the reasonable use of Rhus extracts.

That four members of one family should suddenly develop side-reactions after taking only three tablets when thousands of patients have completed an entire course of 200 tablets without complaint is highly improbable. Did the members acquire an old fashioned case of poison ivy dermatitis after a family picnic? "Guilt by association" is as much a problem in medical science as in politics.

ALBERT M. KLIGMAN, M.D.
University of Pennsylvania
University Hospital
Philadelphia 4.

To the Editor:—Dr. Kligman's skepticism is appreciated. Before reporting these cases careful evaluation of data forced us to conclude that Aqua Ivy, AP, was the offending agent. The reactions were so severe that further administration of Aqua Ivy, AP, for absolute proof, was deemed dangerous. Experience has taught us that any complex chemical given as a drug eventually will produce some reactors. Never, before the over-the-counter distribution of Aqua Ivy, AP, has there been such mass exposure to an antigen. Dr. Kligman states that there was no good evidence of kidney damage from the reasonable use of poison ivy extracts, but in the summary of his fine article (*A.M.A. Arch. Dermat.* 77:149 [Feb.] 1958) he states, "The unusual consequence of Rhus dermatitis includes eosinophilia, kidney damage, etc." If we produce ivy dermatitis by oral administration of poison ivy extract, as took place in one of our patients, then sooner or later, with the widespread use of the antigen, there are going to be unfortunate incidents. These cases did not follow a family picnic. "Old-fashioned poison ivy" shows no joint symptoms and purpura. Connecticut's April is a poor month for family picnics. We believe that it is hazardous to give any antigen to the general population without medical supervision.

THE LEISURE CORNER

THE PIPE COLLECTOR

The immortal Sherlock Holmes, favorite fictional detective of thousands of doctors, had a characteristic appearance which included a cape, a deerstalker hat, and a smoking, curved pipe. The pipe served Holmes as a silent companion, as it has countless generations of devotees. Its early beginnings make an interesting story.

The pipe was known to Europeans even before the introduction of tobacco. Evidence to this effect has been obtained as a result of many archaeological excavations. For example, the ancient Celts smoked aromatic herbs in iron pipes of their own making, and the early inhabitants of Holland, Ireland, Italy, Germany, and Russia left behind pipes made of iron, terra-cotta, and earthenware. Pipes were used in Europe for smoking medicinal herbs for many years before Europeans learned about smoking tobacco. Pleasure smoking on an increasingly wide scale began with the American Indians who introduced pipes to the white men. The Indians smoked a ceremonial pipe, with a bowl made of red sandstone, called a peace pipe or calumet. The tobacco pipe was introduced to Europe in 1586 by Sir Ralph Lane, commander of a group of colonists in Virginia, who dispatched a pipe to Sir Walter Raleigh. Pipe smoking soon became popular. Under Louis XIV, whose military victories sent French soldiers into adjoining countries where smoking a pipe was an established custom, the fad spread throughout France. In Casanova's memoirs, he speaks of his pipes almost as fondly as he does of his women.

The 17th and 18th centuries brought the vogue of the pipe into popular and general use, and also into casual conversation. History tells us that LaSalle, one of Napoleon's courageous cavalry leaders, always entered battle with a pipe held firmly between his teeth. It is related that he once captured an enemy general who refused to surrender his meerschaum pipe. LaSalle, however, "marched back to camp with the pipe and its owner." Soon thereafter, many of Napoleon's generals created a fad—collecting pipes. Napoleon would refer to these pipe collections as his arsenal of pipes.

The use of the pipe has not always been restricted to the smoking of tobacco. The truth is mankind has always seemed to smoke something. Coltsfoot was once smoked as a sedative for coughs, and asthmatic patients have puffed away at pipes to relieve their attacks. The pipe-smoking custom has extended to the Pacific islands, India, Siberia, Peru, Bolivia, Turkey, and China. Their inhabitants smoke pipes filled with fungus, cocoa, hashish, opium, and a species of hemp, tea, lavender, aniseed, hops, and sunflower seed. Hindus, whose pipe-smoking habits are supposed to be more refined than others, mix all sorts of products in their pipes—sugar, nutmeg, and even ground bananas moistened with rose water.

Pipe-collecting hobbyists invariably number at least one clay pipe in their collection. Pipes with bowls made of clay, porcelain, or the clay-like meerschaum are popular. Porcelain is an excellent conductor of heat and since it is quite fragile, it is more frequently employed as a showpiece than as an actual smoking vehicle. Porcelain lends itself to many beautiful patterns and shapes, and artists, working with ceramics, often enjoy producing pipes that are original creations. Meerschaum, a soft, whitish mineral similar to clay, is often used to make pipes. The material is so light that it will float in water.

Should anyone be interested in devising his own meerschaum pipe, here is a working formula. Meerschaum is a compound of magnesium, silicon, oxygen, and water. Crude magnesium silicate is boiled in milk, then kneeded in wax and linseed oil. Before being treated, the material has a dirty white appearance, but after it is rubbed and polished, it acquires a lily-white hue. The substance is then cut in a block and the bowl shaped. It is then glazed and polished with pumice stone, lime, and tallow. Good workmanship will convert meerschaum into a handsome item, a proud addition to a collection of artistic pipes.

Wood pipes are sought by many collectors, especially the rosewood pipe, which is made of the delicately scented wood of the Brazilian rose tree. Of medium hardness, the color ranges from purplish brown to burnt sienna. The cherrywood pipe is made from wood of the wild cherry, while a Moorish pipe consists of mutton bone and a copper tubing. This pipe has a small bowl and holds but little tobacco. Most pipe racks are never complete without the presence of a brier root pipe. The brier is a shrubby plant of the heath family, and its roots are used for making pipes. The root is thick, close-grained, and hard, and has become the most popular material for making pipes in America and Western Europe. Among the most curious pipes that one can gather for a collection are the hookahs, which are smoked in various parts of the Near East. The bowl of the hookah fits into an airtight vase which is partly filled with water. From the bowl a tube passes downward below the surface of the water. A second flexible tube with a mouthpiece fits into the side of the vase above the water surface. In this way the smoke is cooled and loses much of its "bite."

The pipe-collecting hobby is rooted in generations of pleasure. As one authority on pipes has written, "One would think less of drowning a dog than of throwing a pipe into the dustbin—but then a dog cannot be awakened, but there will always be found men everywhere who will awaken a pipe."

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

The Postmitral Commissurotomy Syndrome: A Four-Year Clinical, Pathologic and Serologic Study, and Its Relation to Restenosis. P. Lisan, A. Reale and W. Likoff. Ann. Int. Med. **50:**1352-1358 (June) 1959 [Lancaster, Pa.].

The authors report on 47 women and 31 men, between the ages of 30 and 50 years, who underwent mitral commissurotomy between January, 1954, and June, 1955. The postmitral commissurotomy syndrome, i. e., a phasic recurrent low-grade fever associated with incisional and/or pleuritic pain, occurred in 21 patients (27%), 18 of whom were women and 3 were men. The first attack occurred within one month after the operation in 7 patients, and as late as 10 months in 4 patients. The syndrome developed within 4 months postoperatively in 17 patients (80%). Multiple attacks occurred in 13 patients. The interval between attacks varied from 1 to 4 months in 6 patients, and the intervals were greater than 4 months in 7 patients. The duration of the attacks varied and did not follow any specific pattern. The pericardial friction rub was the characteristic physical finding. The erythrocyte sedimentation rate was elevated in only 3 patients. A rise in antistreptolysin and antihyaluronidase titers occurred in only one patient. Biopsies of the atrial appendage revealed evidence of chronic rheumatic carditis in 3 of the 27 patients. In none of the patients was that type of Aschoff's nodule seen which Tedeschi and Wagner suggest as pathognomonic of acute or recurrent active rheumatic carditis. Therapy consisted of administration of salicylates, cortisone, hydrocortisone, and antibiotics in conjunction with other usual symptomatic treatment. Restenosis of the mitral valve did not occur in any of the patients with postmitral commissurotomy syndrome.

These observations suggest that the postmitral commissurotomy syndrome is a clinical entity, which is readily distinguishable from the active rheumatic state, and which is characterized by recurrent fever and chest pain after mitral valve surgery. Laboratory and serologic studies and biopsies of the atrial appendage are of little positive value in diagnosis. These studies, however, add more weight to the belief that reactivation of the rheumatic state has no relationship to the postmitral commissurotomy syndrome.

The "Silent Coronary": The Frequency and Clinical Characteristics of Unrecognized Myocardial Infarction in the Framingham Study. J. Stokes and T. R. Dawber. Ann. Int. Med. **50:**1359-1369 (June) 1959 [Lancaster, Pa.].

Within the frame of an epidemiologic study of the cardiovascular diseases set up by the U. S. Public Health Service in Framingham, Mass., the authors studied the clinical manifestations of 65 men and 8 women, between the ages of 30 and 59 years, with myocardial infarction, with special reference to thoracic discomfort. Of these 73 patients, the myocardial infarction was clinically unrecognized in 15; 8 of the 15 denied any precordial pain whatsoever. Careful analysis of the data obtained from the 15 patients with unrecognized infarction and of those obtained from the 58 patients with recognized infarction failed to show any significant differences between the 2 groups regarding age, sex, occupation, weight, or blood pressure. Both groups had consulted physicians with about equal frequency for reasons other than coronary disease during the period in which the infarcts occurred. There was, however, a difference in the prevalence of anginal pain after myocardial infarction in the 2 groups. Although no characteristic clinical pattern of "silent" myocardial infarction was determined, anginal pain was significantly less frequent after unrecognized infarction, and there were also some differences in the electrocardiographic position of the myocardial infarction in the 2 groups. Of the 10 anterolateral myocardial infarctions, only 1 was clinically unrecognized; 8 (53%) of the 15 clinically unrecognized infarcts were posterior in position, and 6 (40%) were anteroseptal.

The fact that unrecognized infarction was less frequently followed by anginal pain than were recognized infarcts supports the suggestion that the pathogenesis of pain associated with angina pectoris is qualitatively similar to that of infarction, and differs only in degree. It would also appear that the "silent coronary" most often resulted from infarction of the anterior left ventricular wall and

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

septum, or the posterior wall, but the numbers are small, and additional data will have to be obtained to confirm this finding. This study emphasizes the importance of laboratory studies in the differential diagnosis of precordial discomfort.

Trigger Mechanisms in Asthma. R. H. Overholt. Dis. Chest 35:587-596 (June) 1959 [Chicago].

Irreversible structural changes in the bronchial system of patients with asthma may act as "trigger mechanisms." The author relates some experiences in the search for, and in the treatment of, structural abnormalities which act as "trigger mechanisms." In the past, the attention of most surgeons centered on interventions which interrupted the nerve pathways to the lung; structural abnormalities were not searched for and corrected, although overlooked "triggers" possibly contributed to the disappointing results. Patients with intractable asthma should have the benefit of a thorough investigation, particularly (1) those whose illness was initiated by an attack of pneumonia, (2) those who have frequent colds in the chest, (3) those who have productive cough, (4) those who have a unilateral wheeze, (5) those who have chest discomfort or pain, and (6) those in whom there is systemic evidence of a focal infection, such as arthritis.

Routine chest films may reveal nothing in patients with asthma, and visualization with contrast mediums is necessary if the presence, nature, and extent of a structural abnormality in the bronchial system are to be determined. Since asthma has been considered by many to contraindicate bronchography, the author shows how the risk can be minimized. Bronchography is deferred until maximum improvement of bronchospasm has been effected. Discussing the interpretation of the bronchographic findings, the author says that structural abnormality is clearly indicated if saccular or tubular dilatation, incomplete stenosis, distortion, crowding, or abnormal spread of branches is found. Complete lack of filling of a segment means one or 4 things: *(a)* technical failure; *(b)* localized bronchospasm; *(c)* mucous plug; or *(d)* structural abnormality.

Surgical exploration permits direct inspection of the lung and testing of segments as to inflow and egress of air. Mechanical defects can be corrected forthwith, and sympathetic, parasympathetic, or both denervations carried out simultaneously. The author explains the value of surgical exploration and the elimination of "trigger mechanisms" in the histories of 3 illustrative cases. The first case report shows the severity and disabling nature of the disease for which bilateral surgery was required. In the second case, the "trigger" was abolished without sacrificing any pulmonary tissue. In the third, an unsuspected "trigger" was discovered at exploration and easily corrected.

Evaluation of So-Called Pleural Indurations. E. Frenk. Schweiz. med. Wchnschr. 89:505-509 (May 9) 1959 (In German) [Basel, Switzerland].

The author briefly discusses the importance of the correct etiological identification of acute pleural effusions. It has been established that tuberculosis accounts for only a minor portion of these effusions, many being caused by neoplasms or pneumonia, and some by pulmonary infarcts, leukemia, uremia, pulmonary abscesses, and abdominal diseases; and in some cases the origin remains unexplained. If a pleural effusion persists for a time, pleural induration or thickening results from the organization of the fibrin deposits on the pleura. The differentiation of the etiology is especially important in the case of tumors in the pleural space and of pathological processes in the pulmonary parenchyma. The author demonstrates this on the basis of the histories of 3 patients, one of whom had a mesothelioma, one a fibrosarcoma, and one a residual empyema in the thickened pleural cupula, in the presence of an old tuberculous process.

Since residual effusions with pleural thickening may become reactivated even after decades of quiescence, and then generally produce atypical disease, it is essential that every patient with pleural induration be subjected regularly to follow-up examinations. Reactivation is demonstrated on the basis of case histories. These illustrate, among others, subacute reactivation of a tuberculous residual empyema that had caused pleural thickening or acute reactivation of residual tuberculous empyemas by mixed infection, trauma, or tumor; finally, as the result of increasing shrinkage and calcification, a pleural induration can cause rapidly progressing circulatory disturbances—in one case precordial venous stasis.

The Isolation and Characterization of a Purified House Dust Allergen Fraction. W. E. Vannier and D. H. Campbell. J. Allergy 30:198-218 (May-June) 1959 [St. Louis].

For many years aqueous extracts of house dust have been used for diagnostic tests and hyposensitization. The authors cite studies carried out by others on the chemical properties of the skin-reacting materials in house dust. They themselves have fractioned aqueous extracts of house dust and mattress dust with ammonium sulfate and a variety of organic solvents. In general, most of the fractions were of a similar order of activity by direct skin test. The least soluble materials had the higher nitrogen content (2 to 5%), while the more soluble fractions had lower nitrogen contents (0.3 to 2%). The authors describe the isolation and characterization of an active dust allergen fraction, low in both nitrogen and color and consisting predominantly of a heterogeneous mixture of acidic polysaccharides.

Some persons who reacted to commercial preparations did not react to the purified material prepared by the authors. This could be due to the particular relationship, in the various preparations, between the concentrations of materials of the same allergen specificity and the patient's threshold of skin reactivity. Another more likely explanation is that more than one allergen specificity is involved and that there are materials with allergen specificities in the less purified commercial preparations that are not present in the purified material. It is reasonable that clinical house dust allergy may be associated with a number of different allergen specificities. It is also possible, however, that some of the reactions obtained to the less purified fractions are due to the presence of other known allergens (for example, animal danders or pollens in the original house dust). The type of dust used to prepare the extracts may also be a factor. The material with which the authors started their studies contained large amounts of mattress dust which may be deficient in some of the allergen specificities normally found in house dust.

The dust fraction was found to be heterogeneous by electrophoretic and sedimentation analysis. Two main peaks were demonstrated by electrophoresis. The chemical composition was found to be roughly 5% polypeptide and 95% polysaccharide, with about equal amounts of uronic acid (probably glucuronic acid), D-glucose, D-galactose, and D-mannose as well as lesser amounts of L-rhamnose and L-arabinose. Even though the problem of the chemical nature of the specific house dust allergen has not been solved, these studies revealed new information about the nature of materials that have been used clinically for the past 30 years.

Peripheral Neuropathy in Myxedema. L. E. Crevasse and R. B. Logue. Ann. Int. Med. 50:1433-1437 (June) 1959 [Lancaster, Pa.].

Of 65 patients with spontaneous myxedema reported on by the authors, 31 (47%) had peripheral neuropathy manifested by severe lancinating pains in the extremities and/or paresthesias. It was the presenting and dominant complaint in 2 women, aged 39 and 58 years, respectively, and in a 66-year-old man. The neuropathy may be the initial manifestation preceding the more overt symptoms of myxedema. Because of anemia, pallor, and neuropathy, myxedema is frequently confused with pernicious anemia. The motor and sensory symptoms are out of proportion to neurological findings, and may be confused with a primary degenerative disease of the central nervous system, nerve root compression, or hysteria. The neuropathy is completely reversible, regardless of the duration of the illness, and will resolve on adequate thyroid replacement therapy alone.

Gastrointestinal Protein Loss in Idiopathic-Hypercatabolic Hypoproteinemia. M. Schwartz and S. Jarnum. Ugesk. læger 121:689-696 (April 30) 1959 (In Danish) [Copenhagen].

In 4 patients with so-called idiopathic or essential hypoproteinemia of long duration, there was high albumin degradation (hypercatabolism), and by means of radioactive polyvinylpyrrolidone an abnormally high permeability to molecular substances in the gastrointestinal canal could be established in all the cases. The hypoproteinemia was due to a loss of protein in the lumen of the digestive canal and was thus a symptom of disease there (hypertrophic gastritis, disease of the small intestine).

Hypoglycemic Effects of Phenethyldiguanide (DBI): Clinical Study of Juvenile and Brittle Diabetes. A. Amador and R. Rodríguez. Rev. invest. clín. 11:11-33 (Jan.-March) 1959 (In Spanish) [Mexico, D. F.].

This report on the hypoglycemic effects of phenethyldiguanide (DBI) comprises 3 studies made at the diabetes clinic of the Hospital for Nutritional Diseases in Mexico City. The first study consisted of a glucose-tolerance test given to 4 diabetic patients and to a control group of 4 normal subjects. After determination of fasting glycemia, 100 mg. of glucose was administered orally to all the subjects; then postprandial glycemia was determined every hour for 5 hours. The test was repeated a week later, this time with administration of DBI in doses that varied from 100 to 250 mg. Phenethyldiguanide did not modify the glucose tolerance in the normal subjects, but produced slow and moderate glycemic decrease in the diabetic patients.

The second study was made with 2 hospitalized patients with uncomplicated diabetes, one requiring 20 units of insulin, and the other 40 units. These patients received a daily dose of 150 mg. of DBI during 2 weeks. Fasting and postprandial glycemia was determined, and glycosuria was checked during the whole treatment. Laboratory blood, urine, and liver-function tests were performed. After a 2-week interval the same treatment was repeated. The over-all results indicated definite effects of DBI on postprandial glycemia.

The third study consisted of prolonged administration of DBI to 12 outpatients with uncomplicated diabetes. Five were juveniles requiring high doses of insulin and suffering from so-called brittle diabetes. The other 7 were adults with varied insulin requirements. Laboratory blood, urine, and liver-function tests were also performed. The administration of DBI was started only after stabilization of the diabetes with a uniform dose of insulin, which required from 1 to 3 months according to the individual conditions. The initial dose of DBI was 150 mg. daily. The maximal dose was 250 mg., which was reduced to 200 mg. when symptoms of intoxication appeared. In both the juvenile and the adult groups there was decrease in glycemia, and the dose of insulin could be gradually reduced according to the degree of glycosuria, glycemia, and the clinical symptoms. The result of the treatment was satisfactory in 10 of the 12 patients, which is significant since none of the patients had moderate diabetes, and 8 had an insulin requirement of 40 to 100 units at the start of treatment. Toxic manifestations from DBI were only of a digestive character (nausea, vomiting, occasional diarrhea) and were controlled by administration of pancreatic extract. The authors attribute the significant effects of DBI on brittle and juvenile diabetes to enzymatic blocking of the action of glucagon and epinephrine, inhibition of glyconeogenesis beginning with the amino acids, and increase of anaerobic glycolysis.

Plasma Prothrombin in Liver Disease: Its Clinical and Prognostic Significance. G. Mindrum and H. I. Glueck. Ann. Int. Med. 50:1370-1384 (June) 1959 [Lancaster, Pa.].

The well-known clinical observation that a low concentration of plasma prothrombin, which does not respond to the administration of vitamin K, indicates serious liver disease prompted the authors to determine the plasma protein level in 82 patients with primary liver disease. A synthetic substrate, *p*-toluenesulfonyl-l-arginine methyl ester (TAMe), was used to determine the plasma prothrombin concentration. As controls, 24 patients with severe systemic disorders, including infection and neoplastic, metabolic, degenerative, and collagen diseases, were studied. The TAMe assay of the plasma prothrombin level differs from the one-stage methods in that it measures prothrombin and its product thrombin in terms of thrombin yield rather than clotting times. Previous studies had shown that the TAMe assay was unaffected by deficiencies of blood clotting factor VII, fibrinogen, and factor V, which affect one-stage methods of determining plasma prothrombin levels to a considerable degree.

Results showed that the TAMe assay of prothrombin correlated well with the clinical status of the patient with liver disease. Extremely low levels were found in patients with fatal cirrhosis of the liver and in patients with fatal massive necrosis of the liver. Patients with severe cirrhosis of the liver had persistently low values for months or years, whereas patients with viral hepatitis showed higher values and more rapid changes. Patients with serious or fatal liver disease showed little or no improvement in the prothrombin assay after the administration of vitamin K_1 emulsion, in contrast to those with viral hepatitis who showed prompt improvement. The true prothrombin levels invariably lagged behind more rapidly recovering accessory factors.

Comparison of the results of the TAMe assay with those of standard liver function tests showed that a good correlation exists between the findings on the TAMe assay and the albumin-globulin ratio test, and an excellent statistical relationship was observed between the TAMe assay and the Bromsulphalein retention. The TAMe assay of the plasma prothrombin level may be employed in patients with acute or chronic liver disease, and it is not influenced by the degree of jaundice. Since the assay measures a specific product of the liver, it serves as a useful liver-function test. Serial assays yield excellent prognostic information.

The Course of Sarcoidosis and Its Modification by Treatment. D. G. James and A. D. Thomson. Lancet 1:1057-1061 (May 23) 1959 [London].

The authors compared in 200 patients with generalized sarcoidosis, which had been confirmed by histological evidence of sarcoid tissue, the results of antituberculous and corticosteroid therapy with the outcome in untreated patients. The response to treatment was assessed by the clinical, roentgenologic, and microscopic findings before, during, and after treatment. The clinical manifestations of sarcoidosis in the untreated patients either showed a high incidence of spontaneous remission or persisted unchanged. No significant improvement could be attributed to antituberculous therapy. There was an early clinical improvement with corticosteroids, and this was more dramatic if the lesions were acute or transient rather than chronic or persistent. Thirty-seven of 47 patients with bilateral hilar lymphadenopathy and 19 of 36 patients with pulmonary mottling eventually showed clear chest roentgenograms without treatment. The roentgenographic improvement was better in the untreated patients than in those receiving antituberculous or corticosteroid drugs. This was possibly due to the delay in beginning treatment. Spontaneous resolution of the abnormalities in the chest roentgenogram was less likely if there was concomitant cutaneous or ocular sarcoidosis. Although this held for the untreated patients and those receiving antituberculous drugs, it was not evident in the patients treated with steroids in whom the incidence of roentgenographic clearing was similar in the presence or the absence of extrathoracic sarcoidosis. Roentgenographic evidence of bone cysts remained unchanged in untreated and treated patients.

Microscopic evidence of sarcoid tissue persisted in most of the untreated patients or those receiving antituberculous drugs but was profoundly modified toward a nonspecific inflammatory reaction in most patients receiving steroids. Reactions to the Kveim test reflected the activity of the disease in untreated patients; due to cellular modification, the reaction to the Kveim test may be suppressed clinically, and the tissue findings may be obscured by corticosteroid therapy; the patients' reactions to the Kveim test were not influenced by antituberculous drugs. The differences in behavior and course of subacute (or transient) and chronic (or persistent) sarcoidosis are stressed, since they influence the evaluation of any regimen of treatment. Triamcinolone is the current steroid preparation of choice. It is principally given in subacute sarcoidosis to prevent progression to a stage of chronic irreversible fibrosis, and it is given in the chronic disease for symptomatic relief. There is no indication for administration of the potentially toxic antituberculous drugs, either as a prophylactic or as a therapeutic measure, in sarcoidosis.

Primary Amyloidosis: Hematological Aspects. J. Jamra, R. M. B. C. Laurenti, T. Verrastro, T. de Brito and others. Rev. Hosp. clín. 14:76-82 (March-April) 1959 (In Portuguese) [São Paulo, Brazil].

Two patients suffering from primary amyloidosis, a much rarer disease than the secondary form, were treated at the Hospital das Clínicas, University of São Paulo. In both cases the amyloidosis was complicated by hematological disorders. In one patient the complication was thrombocytopenic purpura, an association that has not been mentioned before in the medical literature. In the other patient the complication was hemolytic anemia. In neither case was a definite favorable response to hormonal therapy and/or splenectomy obtained.

In the first patient, a 44-year-old woman, the onset of the disease had been marked by weakness of 4-month duration followed 2 months later by cutaneous hemorrhages. One month before being admitted to the hospital, she had had a prolonged menstrual period which led her to seek medical advice. After the diagnosis of thrombocytopenic purpura was established, the patient received 0.9 cc. of epinephrine daily for 10 days. During this period there was improvement of the cutaneous hemorrhages, but the hematological condition remained unchanged. Corticotropin (ACTH) was then administered in daily doses of 40 units during another 10 days, followed by the administration of prednisone (150 mg. daily) for 7 days. Melena occurred on the second day of prednisone therapy. The medication was suspended, but 4 days later the patient suffered a cerebral accident diagnosed as ischemia caused by hemorrhage or anoxia. An emergency splenectomy was performed; the following day hematemesis and fall of blood pressure occurred, and the patient died.

The second patient, a 45-year-old man, had had a diagnosis of hemolytic anemia 2 years before admission to the hospital. He had been treated with prednisone, nitrogen mustard, and blood transfusion and had undergone splenectomy. A new treatment was given with prednisone in daily doses of 150 mg. The patient was discharged after 40 days, during which he had gained weight and his condition had improved. This remission lasted for approximately 4 months. The patient was rehospitalized following the return of intestinal and cardiac symptoms and died 24 days later. The authors believe that amyloidosis was, in these 2 cases, the primary condition and the causal factor of the hematological disorders, and they advise that primary amyloidosis should always be investigated as a possible cause in erythrocyte and platelet alterations.

Progressive Chronic Polyarthritis Treated with Prednisone: Development of Peripheral Neuropathy and Periarteritis Nodosa, and Death: Case Report. J. Rotés-Querol, J. Surós and E. Lience. Med. clín. 32:113-116 (Feb.) 1959 (In Spanish) [Barcelona, Spain].

The development of periarteritis nodosa in patients with polyarthritis has become much more frequent since the introduction and wide use of adrenal steroid therapy. In the case reported, the association of polyarthritis with periarteritis nodosa was further complicated by the development of polyneuritis, which, as a rule, is not present in the clinical picture of chronic polyarthritis. The patient, a 65-year-old man, first experienced pain in his right shoulder and arm, which after a period of remission extended to his lower extremities. He was first seen by the authors 11 months after the onset of his disease; he had already received about 6 Gm. of prednisone and 1.75 Gm. of prednisolone. His condition was poor, cachectic. The dose of prednisone he had been receiving (20 mg. daily) was gradually reduced, and both analgesic and tonic preparations were given with favorable results. The remission lasted for approximately one month. Edema of the lower extremities, dysesthesia, and eventually paresis occurred in succession. The prednisone medication was suspended after an episode of melena and hematemesis. As the articular symptoms recurred, the administration of prednisone was resumed at a small dose (6 mg. daily). A neurovascular syndrome developed, including peripheral sensory and motor polyneuropathy, trophic cutaneous ulcers, circulation occlusion, and gangrene in the lower extremities. The patient died 16 months after the onset of his disease.

The authors consider the development of periarteritis nodosa and its complicating peripheral neuropathy as additional, separate diseases in this patient and believe that the effects of prednisone played a part in producing the complex clinical picture. They relate the toxic effects of adrenocortical preparations to an excess of mineralocorticoids over the glucocorticoids, which becomes manifest during the period of adrenocortical inhibition that follows the suppression of hormonal therapy. It is during this period that periarteritis nodosa usually develops, sometimes associated with peripheral polyneuritis as in the case reported.

Porphyria in Sweden and South Africa. G. Dean and H. D. Barnes. South African M. J. 33:246-253 (March 21) 1959 [Cape Town].

The porphyrias have been classified into acute porphyria, chronic porphyria, and congenital porphyria. This last form was later renamed "erythropoietic porphyria," because in this type the presence of numerous fluorescent normoblasts in bone-marrow films indicated that the marrow was the site of the metabolic anomaly. Other forms were grouped as hepatic porphyria, because excessive amounts of porphyrins or a precursor could be demonstrated in liver tissue. Discussing the inheritance of porphyria, the authors mention Waldenström's studies; this investigator finally deduced that acute porphyria in Sweden was based on non-sex-linked inheritance of a Mendelian dominant type. The studies of Dean and Barnes disclosed a similar inheritance for susceptibility to porphyria among the white population of South Africa and traced the inheritance to a pair of early settlers from Holland. In these cases, however, symptomatology was mixed; acute attacks occurred more frequently in women; cutaneous lesions were commoner and more severe in men; and some cases showed both acute and cutaneous symptoms. This supports Watson's contention that subgroups of hepatic porphyria are varied manifestations of the same underlying anomaly, but the findings in Sweden, where acute and cutaneous manifestations of porphyria do not overlap, are not in agreement with this hypothesis.

A comparative study of Swedish and South African cases was indicated, and to this end Dean visited Sweden, where arrangements were made by Waldenström for him to see a number of patients, including a family in which several members had suffered attacks of acute porphyria. Specimens of urine and feces from these patients and some of their relations were screened for porphyrin metabolites by Dean; quantitative determinations of urinary porphobilinogen and delta-amino-laevulic acid were carried out in Malmö; and the stools were sent to Johannesburg for quantitative porphyrin analysis. Similar studies were carried out on 2 families in Holland.

The results of these studies indicate that intermittent acute porphyria is a different genetic disorder from the condition which presents with acute episodes or cutaneous lesions and sometimes with both. The name "variegate porphyria (porphyria variegata)" is proposed for the latter. The main features whereby these 2 forms can be differentiated are as follows: 1. Cutaneous manifestations, which are common in variegate porphyria, are never seen in members of families with the intermittent acute form. 2. In the latter, excretion of porphobilinogen and delta-amino-laevulic acid continues at a high level, sometimes for years, after the attack has subsided, but in variegate porphyria it returns to normal, or virtually normal, levels as the patient recovers. 3. Raised stool coproporphyrin and protoporphyrin are characteristic of variegate porphyria even during remission from acute episodes, and of latent cases without clinical manifestations. In intermittent acute porphyria, stool porphyrins may be slightly raised during the acute attack but are otherwise normal or nearly so.

The Excretion of Porphyrins and Porphyrin Precursors by Bantu Cases of Porphyria. H. D. Barnes. South African M. J. 33:274-278 (March 28) 1959 [Cape Town].

It has been shown that Swedish patients with intermittent acute porphyria and white South African patients with variegate porphyria, who may present either cutaneous manifestations or acute symptoms, and not infrequently both, differ markedly from each other in their patterns of excretion of porphyrins and porphyrin precursors. Hundreds of cases of porphyria have been seen among the Bantu of South Africa in recent years, and the pattern of excretion in some of these has been determined for comparison with those of the 2 groups mentioned above. The excretion of porphyrins and porphyrin precursors by 15 adult Bantu patients with a cutaneous type of porphyria is reported and shown to differ from findings in patients with intermittent acute and variegate forms of porphyria.

In commenting on the implications of his observations in relation to the etiology and classification of porphyria among Bantu patients, the author points out that there is no conclusive indication of a hereditary factor in the etiology of porphyria among the Bantu patients; this is a marked contrast to the evidence of a Mendelian dominant inheritance for susceptibility to acute intermittent porphyria among the Swedish and to variegate porphyria among the white South African groups. While this gap may be filled in the future, it is also possible that porphyria may be an acquired disease in the Bantu. It has been suggested that a liver, weakened by infantile malnutrition, which is common among the Bantu, breaks down under stress in adult life and that porphyria is one of its manifestations. As regards classification, the author believes that the present status of knowledge points to the necessity of distinguishing 2 groups of cutaneous porphyria in addition to the erythropoietic (congenital) form. In this connection he cites Tio, who culled many cases from the literature and pointed out that the mixed cases (with cutaneous and acute features) tended to commence earlier in adult life, the patients giving family histories more frequently than those with purely cutaneous disease which began later in life and was more often solitary. The latter Tio designated as "porphyria cutanea tarda SS (sensu strictiori)." Waldenström recently proposed hereditary and symptomatic subgroups of porphyria cutanea tarda. Mixed porphyria, in Watson's sense, has not been encountered among Bantu patients; very few have presented with acute manifestations, and none of them has had conspicuous skin lesions.

It is noteworthy that the Bantu porphyria patients, who on metabolic findings seem to lie between the Swedish and the white South African patients, on the basis of clinical manifestations would be placed at the opposite extreme to the Swedish, with the white South African group intermediate. This leads to the inference that Watson's hypothesis that the clinical findings in hepatic porphyria are varied manifestations of a single underlying metabolic anomaly, though true of the white South African patients, cannot be extended to cover all 3 groups. It has been observed that skin sensitivity to solar radiation in humans and to ultraviolet light in albino rats is enhanced after administration of delta-amino-laevulic acid. Cutaneous reactions in the patients under discussion cannot be harmonized with this finding, since the Swedish patients, who would presumably have the highest concentrations of this metabolite in the circulating blood, have no skin lesions, such as are present in many patients in the other 2 groups.

Whipple's Disease: A Clinico-Pathological Study of Three Cases. L. I. Taft, A. G. Liddelow and Mary Ralston. Australasian Ann. Med. 8:129-136 (May) 1959 [Sydney, Australia].

To the approximately 60 cases of Whipple's disease previously reported in the literature, and sometimes referred to as intestinal lipodystrophy, the authors add 3 new cases, all of which concerned men, ranging in age from 44 to 60 years. The clinical course and the autopsy findings in these patients are presented. The authors discuss some of the numerous etiological theories on the condition, pointing out that the theory of an intestinal defect in the handling of fat as the basic abnormality is difficult to accept.

The authors consider the basic abnormality to be a proliferation of mucoprotein-producing reticuloendothelial cells; these cell are maximally concentrated in the small intestinal lymphatic system, but they also occur at other sites, including the peripheral lymph nodes where, in the earliest stages, they can be seen arising in the germ centers. Transitions demonstrable between ribonucleic acid (RNA)-containing cells and cells containing mucoprotein are considered to indicate synthesis of the mucoprotein, rather than its phagocytosis by the proliferating reticuloendothelial cells. Collagenization of lymph nodes and lymphatics is believed to be a result of the activity of these cells and responsible for the observed obstructive phenomena. The stimulus responsible for the proliferation of the mucoprotein-synthesizing cells is unknown. It may represent a highly differentiated neoplastic process. Again, it may be the outcome of some cellular defect—e. g., enzymatic—whereby there is an abnormal accumulation of a normally synthesized mucoprotein. Response to steroid therapy in this condition is compatible with the known reticuloendothelial suppressive action of adrenal cortical steroids. However, this response is not sustained.

Hypertension—Treated and Untreated: A Study of 400 Cases. A. W. D. Leishman. Brit. M. J. 1:1361-1368 (May 30) 1959 [London].

The author compared the course of untreated hypertension in 87 men and 124 women, who had a diastolic pressure initially not less than 100 mm. Hg. with that of hypertension in 73 patients treated by lumbodorsal sympathectomy and in 118 patients treated with ganglion-blocking drugs. The patients were followed up regularly after 1946. Of the 211 untreated patients, 106 have died, and study of their cases confirmed that high diastolic pressure, male sex, and presence of albuminuria or retinopathy were particularly unfavorable features. Changes in the electrocardiogram did not appear to influence the prognosis. Rise of blood pressure in the untreated patients was uncommon, but in 20 of 176 patients (128 of whom survived for more than 5 years and 48 failed to survive 5 years but were reexamined before death), the diastolic pressure increased by more than 20 mm. Hg. Malignant or accelerated hypertension developed in 7 of these 20 patients. This could not have been foreseen when they were originally examined. A satisfactory lowering of blood pressure was achieved in 65 of the 73 patients who underwent lumbodorsal sympathectomy. The unusual permanence of these results was attributed to extensive dorsal denervation. Ganglion-blocking agents were given parenterally; of the 118 patients treated, 25 have since died, and 7 have been treated for less than a year; of the remaining 86 patients, 58 (67%) are now regarded as well controlled, 23 are under fair control, and 5 are therapeutic failures. An adequate hypotensive response was achieved in only 6 of the 25 patients who died.

The treated and untreated groups of patients are judged to have had hypertension of equivalent severity, and comparison of their respective mortality rates has been made in 8 separate categories of hypertension. Except among those with malignant hypertension, the mortality rate among treated patients was in no instance appreciably higher than one-third that among the untreated patients. Although the length of observation of patients treated by drugs is not yet adequate for strict comparison, the statistics leave no doubt that lives have been extended by both the surgical and the hypotensive drug treatment. Reduction in the number of fatal strokes has been a notable feature. Judged from the fate of untreated patients, the employment of ganglion-blocking drugs seems justified in any male patient whose diastolic pressure is consistently above 120 mm. Hg and in the presence of albuminuria may be advisable when the blood pressure is below this level. Female patients with hypertension, however, do not normally require this treatment unless the diastolic pressure is at least 130 mm. Hg.

SURGERY

Pulmonary Resection for Drug-Resistant Cavitary Tuberculosis Utilizing Ancillary Drugs. W. R. Webb. Am. Rev. Tuberc. 79:780-789 (June) 1959 [New York].

Sixty-eight pulmonary resections were performed on 62 patients with persistent cavitary tuberculosis, who ranged in age from 18 to 65 years. All the patients had tubercle bacilli in the sputum of proved or presumptive resistance to streptomycin, isoniazid, and PAS. The duration of total illness ranged up to 17 years, and only 20 of the patients had had tuberculosis for less than 3 years. The patients were previously subjected to operations which included pneumoperitoneum, pneumothorax, and thoracoplasty. Roentgenograms made at the time of admission showed that 41 patients had far-advanced and 21 had moderately advanced tuberculosis. Each patient was given viomycin and pyrazinamide for 2 weeks before the operation and for approximately 3 months after the operation. Six of the patients included in an initial report received thiazolsulfone, which was not used after the more potent pyrazinamide became available. The usual dosage administered consisted of 2 Gm. of viomycin twice a week, with either 1 Gm. of the sulfone 4 times daily or 500 mg. of pyrazinamide 4 times daily. The administration of streptomycin, isoniazid, and PAS was continued in the belief that many of the bacilli in the areas outside the cavity might be susceptible to their action.

The resections in this series included 16 pneumonectomies, 24 lobectomies, 8 lobectomies plus segmental procedures, and 20 segmental resections. These operations presented marked technical difficulties, as dense adhesions, hilar fibrosis, and multiple enlarged adherent lymph nodes were common findings. Significant hemorrhage, due to injury to the vascular structures, occurred in 4 patients, but it was possible to control the hemorrhage and complete the contemplated operation in every patient. Five of the 62 patients died. All deaths occurred early, but none was directly related to the tuberculous disease or to the fact that the infections were resistant to the major antituberculous drugs. The patients have been followed up for from 4 to 56 months. Fourteen patients have shown subsequent tuberculous relapses, such as 2 roentgenologic relapses, 5 bacteriological relapses, and 7 relapses of both types. All but 5 of the patients now have inactive tuberculosis following further drug or surgical therapy.

The author has not noted undue complications after segmental resections, which actually have resulted in far better results than either the lobectomies or the pneumonectomies. The administration of viomycin combined with pyrazinamide appears to be of value as temporary protection for excisional therapy of tuberculous lesions in which the bacilli are resistant to the major antituberculous drugs.

Management of Chylous Extravasation. W. J. Burdette. A. M. A. Arch. Surg. 78:815-831 (June) 1959 [Chicago].

The author presents 3 patients with chylous extravasation observed in the hospitals affiliated with the University of Utah College of Medicine. The first was a 26-year-old man; the second, an infant; and the third, a 2-year-old boy. The first patient has resumed his occupation after the operation. The infant slowly improved on a regimen of repeated paracentesis, transfusions, and administration of albumin. The third patient died, and autopsy revealed chylous effusion into the pleural and pericardial cavities.

The author discusses the etiology, symptoms, diagnosis, and treatment of chylous extravasation on the basis of an extensive literature, a total of 172 references being listed at the end of the paper. The etiology of chylous extravasation may be due to trauma, either surgical or nonsurgical, or to obstruction resulting from neoplasm, infection, thrombosis, and cirrhosis, or it may be idiopathic. Chylous extravasation should be considered as disease of the thoracic duct, but with regard to the symptomatology it can be classified into groups with regard to type and to the time of onset of symptoms. Early in the disease, the appearance of chyle in the abdominal cavity may occur in 2 principal ways. In the first there is painless, cumulative ascites, and most of the symptoms are due to the presence of a large amount of fluid in the abdominal cavity. This type occurs commonly in infants and children, and, because of the patency of the tunica vaginalis, chylocele may be the first thing noted. In adults, chyle may also dissect downward and present in the groin. The chyle may leak in quantities as high as 2 liters per day. The other type of case is that in which the patient's presenting symptoms are those characteristic of the acute abdomen. It is frequently confused with appendicitis, and cases have also been reported in which celiotomy was performed with a preoperative diagnosis of cholecystitis, mesenteric embolism, or perforated viscus. When the thoracic duct has been damaged, there may at first be no symptoms, because time is required for the chyle to break through the pleura or peritoneum into the thoracic or abdominal cavity. When this occurs in the chest, it may be accompanied by dyspnea and a shock-like state, which is relieved by removing the fluid Injury to the duct in the neck may result in a fistula.

The diagnosis of chylous extravasation is usually made by examination of fluid withdrawn from the peritoneal and thoracic cavities or obtained from a cervical fistula or collection. Confirmation is obtained on microscopic examination when material is stained with lipophilic stain. The management of chylous extravasation is most effective if the following principles are observed: 1. The condition is regarded as one involving a single system, the clinical manifestations depending on the locus affected. 2. Conservative management by withdrawal of chyle is limited unless improvement occurs promptly. 3. Surgery is performed early and consists of ligation or excision of the affected portion of the system. 4. Visualization of the ductal system is carried out through the use of lipophilic dyes or angiograms when a question of adequate collateral drainage arises. 5. Supportive treatment is adequate to repair the fluid and nutritional deficit resulting from the leakage of chyle. 6 The surgeon is vigilant both to avoid operative injury to the thoracic duct and to recognize and repair it at the time it occurs.

Resection in the Treatment of Pulmonary Tuberculosis: Statistical Report on 304 Cases. G. D. Bianchera, G. Bozzetti and G Ferrara. Ann. med. Sondalo 7:18-32 (Jan.-Feb.) 1959 (In Italian) [Sondrio, Italy].

The authors report on a statistical study on 304 male patients, 19 to 50 years of age, with pulmonary tuberculosis, who were subjected to lung resection during the period from December, 1951, to April, 1957. Most of the patients had suffered from a chronic form of pulmonary tuberculosis for many years and had received antibiotic treatment and medical or surgical collapse therapy. Only 10% of the patients presented a form of the disease requiring resection. Complete data were available on only 258 of the 304 patients treated, but none of the remaining 46 patients had died at the time the study was made. At operation tuberculosis had been present for more than 2 years in 69.4% of the patients and for from 4 to 8 years in 32%. Segmental resection was performed in 7.8% of the cases, lobectomy in 55%, more extensive resections, including multiple segmental lobectomies, in 9.3%, and pneumonectomy and pleuropneumonectomy in 27.9%. Thirty patients (9.8%) died, 11 (3.6%) of them within 60 days after the operation, and 19 (6.2%) after a period of from 1 to 7 years.

Results classified as "good" were obtained in 183 (71%) of the patients who were followed up. These patients, who returned to normal life, did not suffer any surgical complications or relapses of tuberculosis, and their sputum was negative. Results classified as "incomplete" were obtained in the remaining patients; complications, such as bronchial fistula, empyema, and cor pulmonale, or a relapse of tuberculosis in the residual homolateral or contralateral parenchyma persisted or reappeared.

The patients were divided into 3 groups, according to the previous treatment received and the form of the disease. The first group was composed of 22 patients (8.5%) with unilateral or circumscribed lesions, who before surgery had received only medical treatment, had responded to treatment with antibiotics, and were in a period of stabilization of the disease. The second group was composed of 130 patients (50.4%) in not too severe condition with unilateral lesions not more than 2 cm. in diameter, who had received medical or surgical collapse therapy, and who had had the disease for 4 years. The third group was composed of 106 patients (41.1%) in very poor condition, in whom resection was performed as an emergency operation. Good results were obtained in all 22 patients of the first group, in 98 (75.3%) of the second group, and in 63 (59.4%) of the third group. Results were incomplete in 20 patients (15.3%) of the second group and in 25 (23.6%) of the third group. Twelve (9.3%) of the patients who died belonged to the second group, and 18 (16.9%) to the third group. Obliteration of the residual cavity was performed in 161 (63%) of the patients: thoracoplasty, with or without removal of the first rib, was performed on 90 patients; an extramuscle periosteal plombage with Polystan sponge, on 63 patients; and a diaphragmatic paralysis, on 8 patients. Plombage with Polystan sponge was discontinued in 1954 because of empyema complications resulting from it; a preresectional or postresectional thoracoplasty was substituted, depending on the functional or anatomic condition of the residual parenchyma.

Anatomic Study of Synthetic Vascular Prostheses. P. Gauthier-Villars and P. Ganter. Presse méd. 67:763-764 (April 18) 1959 (In French) [Paris].

The authors made an anatomic study of the grafts of Ivalon implanted in the proximity of the aorta in 4 dogs, which were killed from 10 to 14 months after the operation. At the time of the intervention blood flowed promptly into the porous prosthetic material, from several seconds up to 2 minutes after the operation. A coating of fibrin and blood cells, which had formed on the outer wall of the graft, stopped the blood inflow. A coating of fibrin, from 1 to 2 mm. in thickness, covered the inner wall of the graft from 1 to 2 hours after the operation. Connective tissue from the adjacent areas penetrated into the space filled in afterwards by fibrin. There was no trace of a granulomatous or an inflammatory process taking place where the graft and the host tissue were joined. Formation of thrombosis was very rare.

In the course of the third month after implantation of the graft, the inner coating of tissue in the prosthetic tube became smooth and glossy; it is difficult to say whether this could be considered as a formation of a new endothelium. The grafts were permeable, and there was no evidence of inflammation in the adjacent area from 10 to 14 months after the operation. The lacunas in the graft either were empty or were filled with connective tissue. The graft was surrounded by tissue, which was continuous with the aortic adventitia of the host. The anastomotic areas presented intrusion, but not fusion, of the newly formed graft fibers into the host tissue. A conjunctival-hyaline tissue joined the curved extremity of the artery with the fibrous layer on the internal wall of the graft. The risks of thromboses or intolerance of the host tissue to the graft were minimum. Long-term inspections of operations in which Ivalon or other types of graft have been used as synthetic vascular prostheses will reveal whether this material is cancerogenic, as intimated by Oppenheimer and co-workers.

Relationship of Peptic Esophagitis to Spontaneous Rupture of Esophagus. J. M. Dorsey, R. P. Hohf and T. E. Lynn. A. M. A. Arch. Surg. 78:878-888 (June) 1959 [Chicago].

This report is concerned with observations on 9 patients with spontaneous rupture of the esophagus, observed at the Evanston (Ill.) Hospital from 1946 through 1957. Correct diagnosis was made in 4 of the patients, and operative repair of the esophageal tear performed. All these patients survived. In the remaining 5 patients the diagnosis of an esophageal rupture was established at autopsy. The majority of the patients were middle-aged. However, 3 were under the age of 5 years, and one surgical patient was only 3 days old. Spontaneous rupture of the esophagus refers to esophageal perforation in which there has not been direct external trauma to the esophagus. These cases differ from the much larger group of esophageal perforations that are secondary to instrumentation.

Spontaneous rupture of the esophagus is an acute surgical emergency. The rupture usually takes place during an episode of vomiting. An element of peptic esophagitis may be a predisposing factor. Initially, severe lower substernal, lower chest, or epigastric pain is prominent. There may be associated upper abdominal tenderness and guarding. Lower esophageal rupture should be considered in the evaluation of an acute upper abdominal syndrome. The patient appears critically ill, and a moderate to marked degree of shock is common. Within a short time the features of mediastinitis, with or without associated hydropneumothorax, predominate. Their appearance roentgenographically substantiates the diagnosis. Prompt thoracotomy, with closure of the rupture and adequate drainage of the pleural space, is the treatment of choice. Early recognition and treatment are essential if one is to reduce the morbidity and mortality of this condition.

Balanced Operations for Esophagitis Associated with Esophageal Hiatal Hernia. J. K. Berman and E. J. Berman. A. M. A. Arch. Surg. 78:889-896 (June) 1959 [Chicago].

The authors use the term "esophageal hiatal hernia" to describe the so-called sliding or short esophageal type, and they define this as a cephalad displacement of the cardia of the stomach above the diaphragm. This particular type of hernia is primarily a malfunction of several of the derivatives of the foregut, the parts of the alimentary canal nourished mainly by blood from the celiac axis and concerned primarily with digestion. Therefore, in a significant number of patients there is an association of hiatal hernia with esophagitis, duodenal or gastric ulcer, biliary tract disease, and pancreatitis. Moreover, it is well to look upon the foregut derivatives as having a common mucous-gland system. Esophageal hiatal hernia may be asymptomatic, but the history of patients with associated esophagitis is usually a long story of one or many of the following complaints: postprandial pain and discomfort, substernal burning (heartburn), dysphagia, pyrosis, dyspnea, anginoid attacks, regurgitation, aspiration with cough (particularly at night), vomiting, or hematemesis.

The authors underscore the fact that only a small percentage of patients with esophagitis and hiatal hernia need surgery, and that every patient should receive an adequate trial on medical management before any operative procedure is done. If the disease is refractory, if complications occur, or if associated lesions are present, surgery is indicated. In attempting to remedy the malfunction, operations must be balanced so that there will be (*a*) a restoration of the normal position of the esophagus and stomach, (*b*) a normal esophagogastric angle (angle of His; plica cardiaca), (*c*) a reduction in hyperacidity, (*d*) a ready egress of gastric contents through a widely opened pylorus (relieving intragastric pressure), and (*e*) a correction of any associated disease of the foregut. With this procedure the authors have obtained uniformly good results in a series of 19 consecutive patients who have been followed from 6 months to 8 years. All the patients except one have been relieved of their distressing symptoms, and this one is now improved and does not have esophagitis. There has been no recurrent herniation, and no patient has required further esophageal dilatation. An addendum to this paper states that 9 additional patients with esophagitis and hiatal hernia have been treated with balanced operations. Clinical results to date have been excellent.

Strictures of the Common and Hepatic Bile Ducts: A Study of More than Four Hundred Operations, with One- to Twenty-Five-Year Follow-Up. W. Walters, J. W. Nixon Jr., T. E. Hodgins and J. A. Ramsdell. A. M. A. Arch. Surg. 78:908-915 (June) 1959 [Chicago].

Follow-up studies were made by the Mayo Clinic on 265 patients who had undergone 308 operations for stricture of the bile ducts. All the operations were performed by the senior author. The patients were divided into 2 groups to contrast the 5-to-25-year results with the 1-to-5-year results. In the long-term group 191 patients, who had had 217 operations, replied to the questionnaire, and in the short-term group 74 patients, who had had 91 operations, were included. Approximately 20% of the patients had had 2 or more operations for stricture performed by the senior author. Excellent and good results followed 61% of the operations in the long-term group and 73% of those in the short-term group. Fair results were obtained in an additional 7 and 8% respectively.

The results from choledochocholedochostomy (duct-to-duct) and from choledochoduodenostomy were practically the same in each series, with good or excellent results from 68 and 69%, respectively, in the long-term group, and from 83 and 82% in the short-term group. These operations made up the major portion of the operations, although hepaticocholedochostomy and hepaticoduodenostomy, both single and double, with single or double hepaticojejunostomy were performed in appreciable numbers of cases with almost equally good results, even in the 30 cases in which it was necessary to dissect out both hepatic ducts from the liver parenchyma in order to anastomose them to the duodenum or jejunum. The best results, in general, followed the use of T-tubes as prosthetic devices left in the anastomosis from 6 to 9 months.

Of the 52 women in the short-term follow-up group, 4 had pregnancies that went to term after operation. Many of the patients with good and excellent results have reported 2 or 3 episodes of cholangitis the first year after operation; these then disappeared. This observation is important, because if attacks continue or worsen, it means obstruction of the anastomosis, and further operation is usually necessary. It is of interest that stricture was due to surgical injury in all but one of the 265 patients studied; in the one exception it was due to external trauma to the abdomen. Late deaths were due largely to severe cirrhosis, with and without hepatitis present at the time of operation, or to unrelated causes, such as cardiovascular lesions.

Lymphocysts: A Complication of Radical Pelvic Surgery. F. Rutledge, G. D. Dodd, Jr. and F. B. Kasilag, Jr. Am. J. Obst. & Gynec. 77:1165-1175 (June) 1959 [St. Louis].

A frequent serious postoperative complication of pelvic lymphadenectomy is an accumulation of fluid in the retroperitoneum at the dissection site. The resulting lymphocyst formation produces varying pressure effects on the ureters, bladder, rectosigmoid, and blood vessels and is considered responsible for a prolonged postoperative morbidity. Pelvic lymphadenectomy was performed on 281 patients, 81 of whom also underwent hysterectomy, at the M. D. Anderson Hospital and Tumor Institute of the University of Texas, in Houston, between January, 1955, and July, 1958. Most of the patients had squamous-cell carcinoma of the cervix. Lymphocysts developed in 68 of the 281 patients, an incidence of 24%.

There is no relationship between the incidence of lymphocyst formation and the stage of the carcinoma, though the incidence of the lymphocyst formation seems to be in direct proportion to the extent of the pelvic dissection. The greater the number of pelvic nodes removed, the higher is the incidence of lymphocyst formation, and, furthermore, the greater the number of cancer-positive nodes removed in performing lymphadenectomy, the higher the incidence of lymphocyst formation. It also seems that the incidence of lymphocyst formation is substantially higher when lymphadenectomy follows complete radiation therapy than it is after primary radical hysterectomy with bilateral node dissection. The clinical importance of a lymphocyst is determined by its size and location. The smaller cysts are well tolerated and tend to regress spontaneously. Symptoms attributable to lymphocysts do not become evident clinically until the usual postoperative discomfort has subsided. Of the 68 patients with lymphocyst formation, the conditions of 54 were diagnosed by the third postoperative week. The actual extent and significance of the lymphocyst formation can best be demonstrated by radiographic methods. The effect on the urinary tract and the colon is best demonstrated by pyelographic and barium-enema examination. While the initial symptoms prolong postoperative morbidity, the late complications are most important from the standpoint of survival. Among these are obstructive uropathy with uremia, intestinal obstruction, fistula formation, and infection of the lymphocyst. The commoner differential diagnoses are those of urinary retention, cystitis, hematoma, infection of the incision, and thrombophlebitis.

The patients in this series were given trypsin, 5 mg. intramuscularly, twice daily for 5 to 8 days. The injections were given in the gluteal muscle, starting the day before or immediately after the operation. The use of this drug did not reduce the incidence of lymphocysts, but their average size was reduced. Immediate, though temporary, relief can be obtained by aspirating the fluid, which should be repeated several times. Secondary infection of the lymphocysts requires strict sterile technique. Incision and drainage through the lower abdominal wall or through the vagina are advised if the lymphocysts become infected. Early incision and drainage are required if the lymphocysts obstruct the ureter and damage the kidney. Efforts to develop a method of prevention have not been wholly successful. It seems reasonable to make an effort to ligate those large lymphatic channels that are encountered during the dissection. Near the entrance to the femoral canal, and along the obturator nerve near its exit, large lymph vessels can often be identified and ligated.

Malignant Melanoma of the Anorectum. S. H. Q. Quan, J. E. White and M. R. Deddish. Dis. Colon & Rectum 2:275-283 (May-June) 1959 [Philadelphia].

The authors reviewed the records of all patients observed from 1929 to 1954 on the rectum and colon service of the Memorial Center for Cancer and Allied Diseases, New York City. Among a total of 4,500 patients with malignant tumors of the anorectal region, there were 21 (or less than 0.5%) with malignant melanoma. This incidence and the fact that only 117 cases of malignant melanoma of the anorectal region have been reported in the English medical literature show the relative rarity of the lesion. The ages of the 21 patients (11 men and 10 women) ranged from 27 to 85 years, all but 2 of them being over 40. The majority of the patients had the sensation that an abnormal mass was present, which was believed to be hemorrhoids or polyps, until the true nature of the lesion was determined by histological examination. Rectal bleeding was noted in 14 patients. The bleeding was usually minor in quantity but steady or recurrent, and not unlike that seen in patients with bleeding hemorrhoids. Some type of change in bowel habits was mentioned by 9 patients.

The primary tumor varied in apearance from a small, benign-looking, grape-like growth at the mucocutaneous junction to a large, ulcerating, deeply pigmented tumor occluding the anus. The smallest was a pigmented mole overlying a 1-cm. area of induration, and the largest was 6 cm. or more in diameter, completely obstructing the lumen of the rectal outlet. The majority of the tumors were not ulcerated, and were 3 to 5 cm. in their greatest diameter. At least 10 tumors were pigmented sufficiently to be visible to the unaided eye, the degree of pigmentation varying from a light gray to a violaceous black color. Six tumors showed only microscopic pigment, and 6 others were diagnosed histologically by the pathologist as amelanotic melanoma. In 19 of the 21 patients the melanoma arose in the anal skin or from the mucocutaneous junction, and if the rectal mucosa was involved, it was so only by upward extension. In several cases, although the greater part of the tumor was situated in the rectum, the lower border of the lesion was attached to the dentate line. In only 2 cases did the melanoma unquestionably arise in the glands of the rectal mucosa. Clinical evidence of metastasis developed in at least 12 patients while they were under observation, and none of these lived more than 12 months after the onset of metastasization.

Treatment varied in the course of years. In the 1930's local removal of the melanoma was combined with either external roentgen irradiation or with the application of radium. The longest survival with this treatment was 20 months. In the early 1940's a diverting colostomy was added to the therapeutic procedures, and one patient treated in this manner lived 48 months. The next method employed was abdominoperineal resection of the rectum, and this operation was followed by the 2 longest survivals in this series, namely, 60 and 96 months. When in 1950 lymph node dissection was added to the abdominoperineal resection of the rectum, the survival time decreased rather than improved. The authors feel that preoperative external irradiation, followed by abdominoperineal resection of the anorectum, or abdominoperineal resection of the anorectum, without irradiation, seems to be the treatment of choice. The average survival time of patients in this group was 33 months.

Anastomosis of Superior Vena Cava and Pulmonary Artery in the Surgical Treatment of Certain Congenital Defects of the Heart. A. N. Bakulev and S. A. Kolesnikov. J. Thoracic Surg. 37:693-702 (June) 1959 [St. Louis].

The authors report on a 5-year-old boy with the tetralogy of Fallot, who was operated on in the Institute of Thoracic Surgery of the Academy of Medical Sciences of the U. S. S. R., in Moscow, and in whom an anastomosis was performed between the superior vena cava and the pulmonary artery. The anastomosis was made with the aid of a stitcher with tantalum staples. The postoperative course was smooth. Cyanosis began to decrease from the first postoperative day and disappeared entirely by the time of discharge on the 17th postoperative day. Of 41 additional patients in whom an anastomosis was placed between the superior vena cava and the pulmonary artery, 14 died during the operation or in the postoperative period, 4 of them on the operating table, 7 within the first 24 postoperative hours, and 1 each on the 2nd, 3rd, and 45th postoperative day respectively. This relatively high mortality rate may be explained not so much by the surgical trauma itself as by the imperfect technique and anesthesia, which later was perfected. In 6 patients death was due to acute hemorrhage, and in 2 additional patients it was due to acute hypoxia resulting from poor function of the anastomosis because of disparity of the lumens of the anastomosed vessels. In these 8 patients postoperative mortality could thus be explained by defects of the surgical technique and by wrong indications for surgery. The postoperative course was smooth in those patients who stood the operation well.

Although the authors' experience with the surgical treatment of congenital heart disease with decreased pulmonary circulation by placing an anastomosis between the superior vena cava and the right branch of the pulmonary artery is limited, they feel justified in drawing the following conclusions: 1. The use of such an anastomosis for the treatment of patients with insufficiency of pulmonary circulation has demonstrated its usefulness and effectiveness in the treatment of such cardiac lesions. 2. This operation is not excessively complicated and can be performed by any thoracic surgeon who has mastered the technique of vascular suture. 3. The advantages of this operation as compared with the interarterial anastomosis are as follows: decrease in the overload of the right ventricle; decrease in the overload placed on the system of the pulmonary artery, which leads to the subsequent sclerosis of the pulmonary vessels; considerable increase in the quantity of oxygenated blood; avoidance of recirculation of the blood through the interarterial anastomosis; and avoidance of endarteritis, which supervenes occasionally at the site of the interarterial anastomosis.

Dupuytren's Contracture: A New Concept of the Pathogenesis Correlated with Surgical Management. J. V. Luck. J. Bone & Joint Surg. 41A:635-664 (June) 1959 [Boston].

The author, who has studied palmar and plantar Dupuytren's contracture since 1936, feels that the factor of heredity is the best established of all potential etiological factors, and that neither chronic inflammation, nor trauma, nor neurological or psychological factors are primary etiological agents in this disease. His interpretation of the pathological anatomy of Dupuytren's contracture and his concept of the pathogenesis were evolved from the study of tissues from more than 200 hands and 28 feet with Dupuytren's contracture. The initial and essential lesion is a focus of proliferating fibroblasts. A focus may exist as a solitary lesion in the palmar or plantar fascia, but multiple foci are the rule. In most instances, the fibroblastic focus creates a palpable nodule. The fibrous cords form subsequent to the nodule and are related to its involution. The author differentiates a proliferative, an involutional (contracting), and a residual stage in the development of Dupuytren's contracture.

In the proliferative phase, the nodule is a focus of fibroblasts which resembles a fibroma. Nodules may be solitary or multiple. Multiple nodules coalesce and form a plaque. While the nodules appear to originate in, or to be superficial to, the palmar fascia, they expand toward the surface. This creates a protruding mass easily identified by the palpating finger. During expansion toward the surface the nodule first replaces the subcutaneous adipose tissue and then the deep layers of the skin. With attachment to the palmar aponeurosis and to the undersurface of the skin, the stage is set for the contraction of the involutional process to create a reactive fibrous cord. The contraction of the nodule creates the most prominent aspect of Dupuytren's contracture—the flexion contractures of the palm and fingers. As collagenization and contraction evolve, the nodule becomes smaller and draws in or puckers the surrounding skin. In addition, it may become anchored to an underlying tendon sheath or joint capsule. If, for example, a nodule is over a metacarpophalangeal joint, the contracture draws the metacarpophalangeal joint into flexion. The cord of Dupuytren's contracture represents reactive functional hypertrophy in response to the repeated tension stresses on the band of fascia from which the nodule took its origin. The fibrous cords grow large in persons who use their hands a great deal. As involution progresses, the nodule becomes less well defined until it disappears, leaving only a focus of dense adhesions and the reactive proximal fibrous cord which is almost acellular and tendon-like. This is the residual stage, during which it is not to be expected that vitamins, hormones, roentgen-ray therapy, splints, and various types of physical therapy would have any significant influence. Nonoperative methods are advisable only if the disease is still active and the nodules are in either the proliferative or the early involutional stage. The results of the injection of hydrocortisone acetate into nodules have been disappointing.

According to the method of surgical management, which is based on the author's concept of pathogenesis, it is not necessary to do a radical excision of all of the palmar fascia and associated fibrous cords, it is necessary only to excise the nodules completely. If Dupuytren's contracture is in the involutional stage, procedures which do not include excision of the nodules, such as subcutaneous fasciotomy, will usually be followed by at least a partial recurrence of the contracture. Subcutaneous fasciotomy is applicable, however, after the nodules have undergone involution, and there are fascial cords proximal to the nodules. These cords can be resolved by subcutaneous fasciotomy. Operations, based upon the stage of the pathological process, were carried out during a 10-year period on 206 hands of 154 patients. The over-all results were good in 164 hands (79.6%), fair in 29 (14.1%), and poor in 13 (6.3%).

Current Status of Surgical Treatment of Ventricular Septal Defect. D. A. Cooley. Dis. Chest 35:651-662 (June) 1959 [Chicago].

Of a collected series of 345 patients undergoing operation during bypass for a variety of congenital and acquired cardiovascular lesions, 130 had isolated ventricular septal defect, which appears to be the commonest congenital cardiac defect requiring open heart surgery. Analysis revealed highly satisfactory results among those between the ages of 2 and 15 years. Among 71 patients in this age group there were 5 deaths, or a mortality of 7%. During infancy the risk of operation is substantially higher. However, a salvage of 70% of patients less than 2 years of age justifies operation even in these critically ill patients.

Pulmonary hypertension is frequently associated with ventricular septal defect. As pulmonary vascular resistance increases in these patients, reversal of the intracardiac shunt may lead to cyanosis. The extent of pulmonary vascular changes influences the risk of operation. Although patients with a so-called Eisenmenger's complex, associated with cyanosis, clubbed nails, polycythemia, and right ventricular hypertrophy, are not satisfactory candidates for surgical treatment, the author operated successfully on a number of patients with balanced or combined left-to-right and right-to-left shunts. Future developments may help control the physiological effects of the increased pulmonary vascular resistance and thus make possible operative correction in almost all patients with ventricular septal defects.

Etiology and Pathogenesis of Dupuytren's Contracture. W. Heim and H.-G. Buchberger. Chirurg 30:212-216 (May) 1959 (In German) [Berlin].

Reviewing the history of contracture of the palmar fascia after its first description by Dupuytren in 1832, the authors mention several theories that have been advanced with regard to its etiology and pathogenesis. Its familial occurrence was noted early and suggested a hereditary etiology. Chronic trauma as a possible eliciting factor was also suggested by some of the early investigators. Increased irritability of the sympathetic nervous system, resulting from various causes, including toxic (alcohol, nicotine, lead), but particularly from osteochondritic changes in the cervical portion of the vertebral column, with contracture of the intervertebral foramens, has been suggested by several investigators as possibly contributing to the development of the contracture of the palmar fascia. Changes in the central or peripheral nervous systems, tumor formation, reparative proliferation, and microtraumatic ruptures of fibers of the palmar aponeurosis are other etiological or pathogenetic factors that have been mentioned.

The authors investigated etiological factors in 76 patients with Dupuytren's contracture, and found that 3 factors were encountered most frequently, although they did not always concur; these were hereditary predisposition, trauma, and abnormal tonus of the sympathetic nervous system. A hereditary tendency could be demonstrated in 12 of the 76 patients (15.8%), but since many of the parents of the patients had already died when the lesion became evident in the patients, and since their own children had not yet reached the age of manifestation, it is assumed that the incidence of the hereditary tendency is probably greater than 15.8%. Investigating the role of trauma as a possible etiological factor, the authors found that in 56 of their 76 patients occupations or sport activities were such as to involve chronic trauma to the palmar surface. It proved difficult to demonstrate increased irritability of the sympathetic nervous system, although investigations were made on the vascular nervous systems. Earlier reports on the higher incidence of Dupuytren's contracture in brewery workers and in epileptic patients could be corroborated, but the incidence in epileptic patients was not as high as indicated in earlier reports. The authors feel that the development of Dupuytren's contracture in the epileptics indicates that toxic effects, in this case from drugs given to suppress the convulsive attacks, play a part in the etiology. They conclude that the pathogenesis of Dupuytren's contracture is a complex process in which several etiological factors are involved.

A Clinical Study of 1,000 Consecutive Cases of Mitral Stenosis Two to Nine Years after Mitral Valvuloplasty. L. B. Ellis, D. E. Harken and H. Black. Circulation 19:803-820 (June) 1959 [New York].

A study is presented of 1,000 patients with predominant mitral stenosis, who were operated on by valvuloplasty between 1949 and 1956. This series included 4 groups. There were no patients in group 1, that is, patients without significant symptoms. Group 2 included 19 patients who were somewhat handicapped by symptoms but were able to carry on a sedentary occupation, and the condition was not progressive. The 711 patients in group 3 suffered mainly from pulmonary symptoms, which were usually progressive in nature, and were sufficiently handicapped, so that ordinary activities were significantly limited. If these patients had had overt congestive failure, it had been because of some unusual precipitating cause, such as pregnancy or a serious infection, and they had rapidly recovered from it. Group 4 was comprised of 270 patients with more severe symptoms, who were mostly cardiac invalids suffering from chronic congestive failure or who were maintained in a precarious state of compensation only by vigorous medical means. All but 2 of the 913 survivors of the operation have been followed at least one year, and most of them up to the latest anniversary of their operation from 2 to 8 years ago.

The survival of the patients was better than would have been expected under medical management. Sixty-nine per cent of the survivors of the operation in groups 2 and 3 improved, and 55% of those in group 4. The percentage improved has tended to drop somewhat with succeeding years of follow-up. In group 3, fibrillating patients and those over 40 years of age did less well than those in normal rhythm or under 40. With increasing degrees of mitral insufficiency, the differences were more striking at the end of 5 years than at the end of 1. Patients with preoperative tight mitral stenosis did better than those whose stenosis was less severe. The presence of associated valve disease (usually aortic) of mild degree did not affect the ultimate outcome. The "postoperative" or "postcommissurotomy" syndrome occurred in an estimated 30.8% of patients, but its presence did not have any bearing on the results. A group of 228 patients whose condition deteriorated after substantial improvement persisting at least one year were analyzed. Factors that were found in a significantly higher percentage of these patients than in those who maintained their improvement were mitral insufficiency, unsatisfactorily performed valvuloplasty, and rheumatic fever occurring since the operation.

Interventricular Septal Defects with Associated Major Vascular Anomalies: Report of Three Cases. G. Robinson, P. Glotzer, M. Gilbert and others. Am. J. Cardiol. 3:746-753 (June) 1959 [New York].

The authors present the histories of 3 patients, ranging in age from 6 to 9 years, who were subjected to open heart repair of interventricular septal defects, and in whom unusual associated anomalies were simultaneously corrected. An extracorporeal pump oxygenator of the DeWall type was used in all 3 operations, and elective cardiac arrest was induced with the aid of potassium citrate. In the first of the 3 patients the preoperative diagnosis was complete and correct. At operation a true right-sided aortic arch was found with a retroesophageal patent ductus arteriosus entering the left pulmonary artery. The left subclavian artery arose from the superior aspect of the ductus arteriosus and ascended along the left side of the superior mediastinum. The ductus arteriosus was divided at its

Treatment and Results of
denal Ulcer: A Statistical
Minerva chir. 14:432-435 (A
[Turin, Italy].

The author made a stati
group of 100 male patient
66 years, all of whom but o
gency operation for a per
ulcer during the period b

The incidence of the disease tended to increase progressively throughout this period. There were only 3 operative deaths. One patient died of hemorrhage a month after the operation. Perforation recurred in 3 patients from 4 to 5 years after the operation. Of 94 patients available for follow-up, results were very good in 14, good in 23, moderate in 12, fair in 5, and poor in 34. Long-term postoperative results were slightly better in patients with duodenal than with gastric ulcer. Perforation of acute gastroduodenal ulcer was present in about one-fifth of the patients, most of whom were under the age of 30. Long-term postoperative results were better in patients with acute than with chronic variety of the disease. The incidence of the disease was higher among manual than among white-collar workers. Long-term postoperative results were better among white-collar than among manual workers.

The emergency operation consisting of a suture with omentopexy gave the best results as a lifesaving procedure, whereas resection was better than the former to prevent recurrence. If resection were contraindicated, suture with omentopexy was probably the best choice. Operation by the technique of Taylor presented a higher operative risk, and its long-term results were not superior to other surgical procedures.

Elbow Out of the Window Injuries: A Follow Up Study of 50 Cases. G. R. Rieth. J. Louisiana M. Soc. 111:220-223 (June) 1959 [New Orleans].

An elbow-out-of-the-car-window injury can vary from a mild abrasion to a devastating crushing avulsion resulting in amputation. The author reviews observations on 50 patients treated at the Charity Hospital of Louisiana, in New Orleans, over the last 10 years for injuries sustained from riding with the elbow out of an automobile window. Tables analyzing various aspects of the injuries showed that most of them were multiple fractures. Seven patients had combined fractures of the shaft of the radius, ulna, and humerus with or without dislocation of the elbow; 6 had fractures of the radius and ulna with or without dislocation of the elbow; 5 had fractures of the olecranon and humerus; 5 had Monteggia's fracture-dislocation and fracture of the humerus; and 15 had fractures of single arm bones. Many of these injuries presented large soft tissue avulsions and extensive neurovascular lesions. Muscle avulsions were observed in 16 patients; injuries to the radial, median, or ulnar nerves, in 18 patients; arterial injuries, in 4 patients; and various dislocations, in 19 patients, 13 of which involved the radial head.

Since the majority of injuries were of the open type, thorough debridement was necessary in 35 patients. Open reduction was employed in 23 patients; internal fixation, in 13; bone grafting, in 10; and amputation, in 5. Excisions, grafting, and arthrodesis were necessary in a few patients. From a review of the results, the author gained the impression that in these injuries, where skin coverage is possible, where contamination is not excessive, and where loss from comminution is minimal, a definitive procedure would be in order at the time of debridement, to reassemble the fragments, maintaining them in their proper relationship by internal fixation if necessary. This gives the best chance for early recovery of function and lessened over-all disability.

An Attempt to Prolong the Time-Limit of Cardiotomy Under Hypothermia by Perfusion of the Brain and Provoked Cardiac Arrest. P. Michaud, E. Saubier, H. Viard and others. Semaine hôp. Paris 35:1845-1849 (May 28) 1959 (In French) [Paris].

Experimental studies were carried out in dogs in an attempt to prolong the 8-minute time-limit imposed in cardiotomy under hypothermia. Cooling of the dogs was kept within the admitted limits of 30 C (86 F), but in order to obtain prolongation of the circulatory arrest, the protection of the brain and the heart had to be assured. This was realized by a permanent cerebral perfusion, by means of a sigma-motor pump, utilizing blood previously obtained from a donor that had been given heparin sodium and an overdosage of oxygen. The blood was collected in silicon flasks. Cardiac arrest was obtained, after clamping the ascending aorta, by an injection above the clamp of potassium citrate combined with heparinized oxygenated blood. Cerebral perfusion was performed by directing the blood toward the brain by means of a simultaneous triple clamping of the aorta above the right brachiocephalic trunk and below the left subclavian artery, the perfusion being given into the right subclavin artery below the 2 carotid arteries.

At the beginning, the amount of blood given was about 3 to 4 cc. per minute per kilogram of the dog's body weight. In order to save blood, and also to take advantage of the hypothermic protection of the brain, perfusion was always begun with a slight delay of 3 to 5 minutes after clamping, or in practice immediately after dilatation of the pupils had started. It was continued without interruption for 20 minutes, which period was arbitrarily determined by the authors as the duration of circulatory interruption. Simultaneously, the cerebral venous reflux was assured by simple gravity into a measuring glass. Overcharge and brain stasis were avoided by the fact that venous return flow was always fairly exactly the same quantity as that of the perfused blood. After the 20 minutes, the heart had to take over both its own circulation and that of the brain. It is, therefore, important that a vigorous cardiac activity with normal tonicity and rhythm be rapidly restored.

some unusual precipitating cause, such as pregnancy or a serious infection, and they had rapidly recovered from it. Group 4 was comprised of 270 patients with more severe symptoms, who were mostly cardiac invalids suffering from chronic congestive failure or who were maintained in a precarious state of compensation only by vigorous medical means. All but 2 of the 913 survivors of the operation have been followed at least one year, and most of them up to the latest anniversary of their operation from 2 to 8 years ago.

The survival of the patients was better than would have been expected under medical management. Sixty-nine per cent of the survivors of the operation in groups 2 and 3 improved, and 55% of those in group 4. The percentage improved has tended to drop somewhat with succeeding years of follow-up. In group 3, fibrillating patients and those over 40 years of age did less well than those in normal rhythm or under 40. With increasing degrees of mitral insufficiency, the differences were more striking at the end of 5 years than at the end of 1. Patients with preoperative tight mitral stenosis did better than those whose stenosis was less severe. The presence of associated valve disease (usually aortic) of mild degree did not affect the ultimate outcome. The "postoperative" or "postcommissurotomy" syndrome occurred in an estimated 30.8% of patients, but its presence did not have any bearing on the results. A group of 228 patients whose condition deteriorated after substantial improvement persisting at least one year were analyzed. Factors that were found in a significantly higher percentage of these patients than in those who maintained their improvement were mitral insufficiency, unsatisfactorily performed valvuloplasty, and rheumatic fever occurring since the operation.

Interventricular Septal Defects with Associated Major Vascular Anomalies: Report of Three Cases. G. Robinson, P. Glotzer, M. Gilbert and others. Am. J. Cardiol. 3:746-753 (June) 1959 [New York].

The authors present the histories of 3 patients, ranging in age from 6 to 9 years, who were subjected to open heart repair of interventricular septal defects, and in whom unusual associated anomalies were simultaneously corrected. An extracorporeal pump oxygenator of the DeWall type was used in all 3 operations, and elective cardiac arrest was induced with the aid of potassium citrate. In the first of the 3 patients the preoperative diagnosis was complete and correct. At operation a true right-sided aortic arch was found with a retroesophageal patent ductus arteriosus entering the left pulmonary artery. The left subclavian artery arose from the superior aspect of the ductus arteriosus and ascended along the left side of the superior mediastinum. The ductus arteriosus was divided at its insertion into the left pulmonary artery. Blood samples drawn from the right atrium and right ventricle after division of the ductus confirmed the presence of a large interventricular shunt. Cardiopulmonary bypass was then established with arterial perfusion through the right femoral artery, followed by elective cardiac arrest. Right ventriculotomy revealed a 2-cm. defect in the ventricular septum completely concealed by the septal leaflet of the tricuspid valve. The chordal attachments of the septal leaflet to the ventricular septum were divided to visualize the defect. The defect was closed with 8 closely placed 3-0 silk sutures. The divided chordae tendineae were repaired. The postoperative course was uneventful.

In the other 2 patients the preoperative diagnosis was not complete. In the second patient the anomalous pulmonary venous drainage was not diagnosed preoperatively. At operation the right ventricle was found to be greatly enlarged. A large anomalous left upper lobe pulmonary vein was seen to drain into the left innominate vein. The remainder of the pulmonary venous drainage was normal. After cardiopulmonary bypass was established and arterial perfusion performed through the left subclavian artery, and after elective cardiac arrest was established, right ventriculotomy revealed a defect in the outflow tract of the right ventricle, which was closed. A side-to-side anastomosis was then made between the left atrial appendage and the anomalous left superior pulmonary vein. The anomalous vein was then ligated and divided at its insertion into the left innominate vein. In the third patient clinical and laboratory methods of investigation established the diagnosis of coarctation of the aorta and interventricular septal defect preoperatively, but the patency of the ductus arteriosus was not detected. The findings at operation were those of a typical coarctation of the aorta with patent ductus arteriosus. The ductus was divided, and the coarctation was excised. An end-to-end anastomosis was then performed between the divided ends of the aorta. Cardiopulmonary bypass was established with arterial perfusion performed through the left subclavian artery. Ventriculotomy revealed a 7-mm. defect in the inflow tract of the right ventricle. This was closed. The subclavian artery was repaired after removal of the catheter. The postoperative course was uneventful.

Treatment and Results of Perforated Gastroduodenal Ulcer: A Statistical Contribution. G. Belloli. Minerva chir. 14:432-435 (April 30) 1959 (In Italian) [Turin, Italy].

The author made a statistical investigation in a group of 100 male patients, aged between 20 and 66 years, all of whom but one underwent an emergency operation for a perforated gastroduodenal ulcer during the period between 1947 and 1956.

The incidence of the disease tended to increase progressively throughout this period. There were only 3 operative deaths. One patient died of hemorrhage a month after the operation. Perforation recurred in 3 patients from 4 to 5 years after the operation. Of 94 patients available for follow-up, results were very good in 14, good in 23, moderate in 12, fair in 5, and poor in 34. Long-term postoperative results were slightly better in patients with duodenal than with gastric ulcer. Perforation of acute gastroduodenal ulcer was present in about one-fifth of the patients, most of whom were under the age of 30. Long-term postoperative results were better in patients with acute than with chronic variety of the disease. The incidence of the disease was higher among manual than among white-collar workers. Long-term postoperative results were better among white-collar than among manual workers.

The emergency operation consisting of a suture with omentopexy gave the best results as a lifesaving procedure, whereas resection was better than the former to prevent recurrence. If resection were contraindicated, suture with omentopexy was probably the best choice. Operation by the technique of Taylor presented a higher operative risk, and its long-term results were not superior to other surgical procedures.

An Attempt to Prolong the Time-Limit of Cardiotomy Under Hypothermia by Perfusion of the Brain and Provoked Cardiac Arrest. P. Michaud, E. Saubier, H. Viard and others. Semaine hôp. *Paris* 35:1845-1849 (*May* 28) 1959 (*In French*) [*Paris*].

Experimental studies were carried out in dogs in an attempt to prolong the 8-minute time-limit imposed in cardiotomy under hypothermia. Cooling of the dogs was kept within the admitted limits of 30 C (86 F), but in order to obtain prolongation of the circulatory arrest, the protection of the brain and the heart had to be assured. This was realized by a permanent cerebral perfusion, by means of a sigma-motor pump, utilizing blood previously obtained from a donor that had been given heparin sodium and an overdosage of oxygen. The blood was collected in silicon flasks. Cardiac arrest was obtained, after clamping the ascending aorta, by an injection above the clamp of potassium citrate combined with heparinized oxygenated blood. Cerebral perfusion was performed by directing the blood toward the brain by means of a simultaneous triple clamping of the aorta above the right brachiocephalic trunk and below the left subclavian artery, the perfusion being given into the right subclavin artery below the 2 carotid arteries.

At the beginning, the amount of blood given was about 3 to 4 cc. per minute per kilogram of the dog's body weight. In order to save blood, and also to take advantage of the hypothermic protection of the brain, perfusion was always begun with a slight delay of 3 to 5 minutes after clamping, or in practice immediately after dilatation of the pupils had started. It was continued without interruption for 20 minutes, which period was arbitrarily determined by the authors as the duration of circulatory interruption. Simultaneously, the cerebral venous reflux was assured by simple gravity into a measuring glass. Overcharge and brain stasis were avoided by the fact that venous return flow was always fairly exactly the same quantity as that of the perfused blood. After the 20 minutes, the heart had to take over both its own circulation and that of the brain. It is, therefore, important that a vigorous cardiac activity with normal tonicity and rhythm be rapidly restored.

The experiments were successful in 7 out of 12 dogs. An important factor in ensuring a good cardiac reanimation is that coronary perfusion should be as large as possible at the time of reactivation of the heart. Induced cardiac arrest does not seem to be incompatible with hypothermia, although it increases the risks involved. The main inconvenience of this technique is that a large amount of stored blood is needed in order to ensure an adequate supply for the coronary circulation after the cerebral circulation has been provided for.

Considerations on Primary Tumors of the Gastric Stump after Resection for Ulcer. C. Colizzi and L. Servadio. Chir. gen. 8:150-169 (March-April) 1959 (In Italian) [Pisa, Italy].

The authors discuss the incidence of primary tumor of the gastric stump in 8 patients, 5 of whom had previously been operated on for gastric ulcer and 3 for duodenal ulcer. Symptoms of the tumor appeared during a period of from 6 to 16 years after the operation for ulcer in 7 patients, and before the 6th postoperative year in 1. The patients were well between the operation for ulcer and the appearance of symptoms of the tumor. Disturbed digestion was the first and only symptom of the succeeding disease. Specific symptoms of the gastric tumor appeared later. Total achlorhydria was revealed in 4 patients, and the malignant process involved the total gastric stump in 4. The correct diagnosis of the tumor was made in most patients at an advanced phase of the disease. The reason for the belated correct diagnosis was that the symptoms after the operation for ulcer were interpreted as postoperative manifestations of the gastric resection for ulcer. The authors believe that an early diagnosis of primary tumor of the gastric stump after resection for ulcer can be made by roentgenologic examination with semifluid barium as the contrast medium. It was possible to perform a radical operation on 5 patients (40%). There were no operative deaths among the patients who underwent the radical operation. The survival period was longer among those who had the radical, rather than a palliative, surgical treatment.

A Rare Case of Duodenal Ulcer with Hemorrhage Being the Only Symptom of the Disease in a Child, 7 Years of Age. V. Ambrosi and A. E. Vaccato. Acta chir. ital. 15:469-480 (May-June) 1959 (In Italian) [Padua, Italy].

A boy, 7 years of age, was operated on for duodenal ulcer. An episode of considerable melena and anemia with no other accompanying symptoms developed a year and a half before the operation. The patient was hospitalized for 20 days and received coagulants which resolved the disorder. A roentgenologic examination of the digestive tract was not illuminating. The patient subsequently had 3 more episodes of melena, not accompanied by other symptoms, and coagulant therapy once more brought about remission of the episodes. A small shadow, the size of a pea, was revealed in the duodenum on roentgenologic examination of the digestive tract and was diagnosed as a duodenal ulcer in the course of the 4th episode of melena. The patient underwent a gastroduodenal resection by the procedure of Hofmeister-Finsterer. The operation was well tolerated by the patient, and the postoperative course was uneventful. The macroscopic finding of the resected material was a duodenal ulcer, which diagnosis was confirmed by microscopic examination. The authors suggest a medical–dietary treatment for duodenal ulcer in childhood before undertaking surgery. If there are recurrent episodes of hemorrhage and an ulcerative lesion, however, these are to be treated by gastroduodenal resection.

NEUROLOGY & PSYCHIATRY

The Periodic Migrainous Neuralgia of Wilfred Harris. E. R. Bickerstaff. Lancet 1:1069-1071 (May 23) 1959 [London].

The author reports on 21 men and 9 women with a special type of recurrent facial pain and headache for which the term "periodic migrainous neuralgia" was coined by Wilfred Harris in 1926. Twenty-three of the 30 patients had their first attack of pain before the age of 40, and the highest incidence was late in the third decade. One 11-year-old boy was the youngest on record. The age of the patients at the time the diagnosis was made differed strikingly from the age of onset, for many patients had had recurrent bouts for a long time. Only 4 patients had had attacks for less than one year, and 10 had experienced attacks for over 10 years, 2 of these for over 30 years. Thirteen gave a history of migraine which had ceased at the onset of neuralgia. Many patients gave a history of migraine in near relatives. Self-administered ergotamine tartrate injections in doses of 0.25 mg., 3 times daily for 5 days out of each week, were given to 16 patients. Twelve patients had complete relief of symptoms from the first full day of injections; 2 had only partial relief immediately, but they obtained complete relief by increasing each injection to 0.5 mg. One patient's nocturnal attacks ceased, but attacks developed at irregular and unpredictable times during the day, and he preferred to discontinue the injections. One patient was a therapeutic failure. Four patients vomited after each injection for the first few days, but this ceased spontaneously without altering the dose. In one 56-year-old patient shortness of breath on exertion and pain in the chest occurred after several months of treatment, but cleared on stopping the injections. In 3 patients the neuralgia was completely controlled, but attacks of ordinary migraine returned. Horner's syndrome developed on the affected side in 3 patients.

The syndrome of periodic migrainous neuralgia is well documented but poorly recognized. It consists of paroxysmal unilateral facial and orbital pain accompanied by autonomic disturbances, arising with clockwork regularity, usually at night, and in bouts lasting several weeks, with spontaneous cessation. The success of treatment by prophylactic self-administered ergotamine tartrate has been confirmed. The high incidence of migraine both in the patients' own past histories and in those of their relatives, a tendency for migraine to occur during control of the neuralgia, the development of migraine at the age of 16 years in the boy who was 11 at the onset of the neuralgia and 13 when the neuralgia ceased spontaneously, and the occurrence of the syndrome in 2 brothers, one of whom had had migraine before the onset of the neuralgia, present sufficient evidence to support the suggestion that periodic migrainous neuralgia is a variant of the migraine symptom-complex.

Alimemazine Tartrate (6549 RP), Its Use in Psychiatric Therapy. A. Fernandez Zoila, J. Basset and M. Lebreton. Presse méd. 67:935-936 (May 9) 1959 (In French) [Paris].

Alimemazine tartrate, an amino derivative of phenothiazine, is a powerful neuroleptic acting upon the central nervous system. Its empirical formula is $(C_{18}H_{22}N_2S)_2$, $C_4H_6O_6$. Its sedative properties make it valuable for use in psychiatric therapy. Fifty women who had had psychiatric illnesses for a long time, and who had had other treatment which was not successful, were given alimemazine tartrate in progressively increasing doses of 400 to 600 mg. by mouth, preferably in the form of drops, and 150 to 200 mg. parenterally, for from 2 weeks to 2 months. The muscular relaxation obtained assured a good emotional readjustment with agreeable behavioral changes. The sedative action on the central nervous system assured regular nocturnal sleep unperturbed by extrapyramidal muscular hypertonicity, without marked somnolence during the day. The authors observed an antidepressive and hallucinolytic action with controlled euphoria and better social adjustment. The usual inconveniences associated with treatment by chlorpromazine and reserpine were not observed. The only examples of intolerance were some lipothymic tendencies without a lowering of blood pressure in older patients and 2 paroxysmal epilepsies in patients with progressive organic disease. Doses were readjusted for these patients without interrupting the treatment.

The 50 patients were divided into 4 groups. Group 1 consisted of 19 women with a long history of psychiatric illness, mostly of organic origin, who were the least influenced by treatment. Group 2 had 16 women with psychotic depression; 8 of these were able to leave the center (Treatment and Social Readaptation Center of Villejuif), and all the others except one showed great improvement. Group 3 consisted of 5 women with psychoses of delirious or schizophrenic structure and of 2 with manic states, all of whom benefited greatly from treatment. Group 4 had 8 patients with psychopathic personalities or serious neurotic manifestations whose conditions were improved by treatment with alimemazine tartrate.

Poliomyelitis: Southern Rhodesia, 1958. D. M. Blair. Central African J. Med. 5:219-223 (May) 1959 [Salisbury, Southern Rhodesia].

In 1958 the author had given an account of the natural history of poliomyelitis in Southern Rhodesia since the end of the 1939-1945 war. This showed that in earlier years the incidence of the disease in the African population had not been high, and, in fact, not until 1957 had the African notifications exceeded those in non-Africans, a very much smaller population group. It was also clear that notification of nonparalytic cases was very rare in Africans and that it was better to compare the race incidence on paralytic cases only. During 1957 the number of cases reported in each of the age groups, 0.4 years, 5-14 years, and 15 years and over, was much the same in the non-African population. However, in the African population the number of cases was far greater in the age group under 5 years. An extensive vaccination campaign was launched in 1957 and was pursued in the face of the prevailing epidemic of poliomyelitis. The amount of vaccine distributed indicated that about all non-African (European) children, from 1 to 15 years of age, had received at least 2 inoculations with vaccine. During 1958 supplies of vaccine in the Federation and Southern Rhodesia were freely available from commercial sources, without limit on the number of doses which could be given or limit on age groups which could be immunized.

The following are the general conclusions of the study of the incidence of poliomyelitis in Southern Rhodesia during 1958: 1. The monthly incidence during 1958 did not resemble the experience of previous postepidemic years, and the scatter of cases throughout the year seems to indicate that the disease was still fairly active and had not settled down to the usual interepidemic state. 2. The higher proportion of cases among Africans seems to have come to stay, although the heavier attack rate among children under the age of 5 years remains a feature in this racial group. 3. Despite the extensive vaccination on non-Africans under 15 years of age, the 1958 experience of incidence by age groups lends no support to the view that vaccination of this group protects it, at least from paralytic accidents of poliomyelitis. Of the 13 cases of poliomyelitis in non-Africans under 15 years of age, 6 were in vaccinated children, 2 of whom had received 3 inoculations. 4. The proportion of paralytic attacks in the vaccinated group of Africans was higher than in the non-Africans who had not been vaccinated. 5. There was, however, some clinical evidence that recovery from the paralytic attacks in vaccinated persons was more speedy than would have been expected from general experience.

Recurrent Paralytic Poliomyelitis: Report of a Case, Documented with Virus Isolations. S. N. Faro. New England J. Med. 260:1177-1178 (June 4) 1959 [Boston].

The author reports on a 3-year-old girl who had a mild but characteristic attack of paralytic poliomyelitis due to type 3 poliomyelitis virus which was isolated in HeLa and monkey kidney cells from the patient's feces. No serologic studies were performed at that time. The patient recovered, with only residual weakness in the internal rotator of the left leg, and remained well for 9 months, until she awoke one morning with a stiff neck and a temperature of 103 F (39.5 C). She was readmitted to the Elizabeth Kenny Institute, in Jersey City, N. J., for considerable weakness of both legs and the abdominal muscles, and on the third hospital day she was in a position of opisthotonos, with almost complete paralysis of the right leg. Type 1 poliomyelitis virus was isolated from stool specimens obtained on the 5th, 6th, and 7th hospital days. The patient was treated with hot packs, stretching, and physical therapy and improved considerably, but the right leg remained partially paralyzed. A brace was applied to this leg, and she will probably have to wear it permanently. Complement-fixation tests were performed on 3 blood specimens; the results were positive for poliomyelitis virus, types 1 and 3. The case of this patient is believed to be the first reported in the literature in which it was possible to isolate 2 different poliomyelitis viruses from one such patient. It also appears to be the first reported case of a second attack of poliomyelitis within a year of the first attack.

PEDIATRICS

Intracranial Calcifications After Tuberculous Meningitis. P. F. Peruzzi. Riv. clin. pediat. 63:94-99 (Jan.) 1959 (In Italian) [Florence, Italy].

Ten children, 6 months to 17 years of age, with tuberculous meningitis, who had been treated at the pediatric clinic of the University of Florence and had been followed periodically from 1947 to 1953, presented intracranial calcifications. Nine of the children also presented neurological, psychic, or endocranial complications. The intracranial calcifications were found roentgenologically during the period of hospitalization (lasting from 10 to 14 months) in 3 patients and from 2 to 5 years after discharge in the remaining 7 patients. They were present in the choroid plexuses in 5 patients, in the suprasellar area in 4, and in the falx cerebri in 1.

The author believes that an intracranial calcification is the result either of certain drugs, such as streptomycin or aminosalicylic acid, which are used in the treatment of tuberculous meningitis, or of a severe form of the disease which, especially when treated late, causes the formation of caseous foci that in time become calcified. Of the 10 patients described by the author, 1 had been treated with streptomycin and sulfone; 4, with streptomycin, aminosalicylic acid, and sulfone; 1, with streptomycin and aminosalicylic acid; and 4, with streptomycin and isoniazid (4 to 6 mg. per kilogram of body weight). An adequate dose of isoniazid prevents the fibrosis or cicatrization that results from the tissue reaction caused by streptomycin; it also facilitates the absorption of necrotic material through vasodilatation; but the dose given to the 4 patients who received the combination of streptomycin and isoniazid was too low to have this effect. The disease was in an advanced stage in the 10 patients when treatment was started.

Tuberculous Meningitis: Clinical and Statistical Data on 332 Cases Received Between Jan. 1, 1953, and Dec. 31, 1956. P. F. Peruzzi. Riv. clin. pediat. 62:159-181 (Aug.) 1958 (In Italian) [Florence, Italy].

Three hundred thirty-two patients, from 2 months to 66 years of age, with tuberculous meningitis were treated in a clinic of the University of Florence from Jan. 1, 1953, to Dec. 31, 1956. Most of the patients received general (oral) and local (parenteral) therapy with various antituberculous drugs. Isoniazid and streptomycin made up the basic therapy and in some patients were combined with aminosalicylic acid, viomycin, or cortisone. Isoniazid was given orally in a dose of 5 to 10 mg. per kilogram of body weight during 1953 and in a dose of 10 to 20 mg. per kilogram of body weight from 1954 on. It was given parenterally to patients with severe forms of the disease and to those who could not receive it orally, being injected into the cisterna cerebellomedullaris in a daily dose of 10 to 25 mg., depending on the age and weight of the patient. Among other forms of parenteral administration, isoniazid combined with streptomycin was injected into the lumbar region in a dose of 1 to 2 mg. per kilogram of body weight. A dose of isoniazid in isotonic sodium chloride solution, 3 to 5 mg. per kilogram of body weight, was administered daily by intravenous drip infusion to 87% of the patients. The course of intravenous injections varied from a minimum of 10 to a maximum of 55 to 60 infusions, depending on the condition of the patient.

Streptomycin was given parenterally in a dose of 10 to 15 mg. per kilogram of body weight (maximal dose, 600 mg. per day); it was also injected into the lumbar region in a dose of 0.5 to 1 mg. per kilogram of body weight. Since 1953 patients with severe forms of the disease or with abdominal or kidney localizations have received aminosalicylic acid in dextrose solution (given always by drip infusion, 15 to 30 injections) in a dose of 100 to 200 mg. per kilogram of body weight. Good results were obtained during 1951-1952 and again during 1955-1956 by using viomycin in the treatment of patients who presented involvement of the auditory system and who had tuberculous disease due to mycobacterium tuberculosis which was resistant to streptomycin. Since 1955 cortisone preparations have been given parenterally, in 10-to-30-day courses, to 92% of the patients; a daily dose of 2.5 to 5 mg. was injected into the cisterna cerebellomedullaris, and a daily dose of 1 to 3 mg. into the lumbar region. Cortisone preparations were given orally only to patients with the severest forms of the disease in a dose of 0.5 mg. per kilogram of body weight or, as beginning therapy for 5 to 7 days, in a dose of 3 to 5 mg. which was gradually reduced.

Two hundred seventy-three patients (82%) recovered, and 59 (18%) died. The following factors affected the course of the disease: 1. Age. Mortality rate among patients up to 2 years of age was 38%, and among those over 40 years it was 25 to 60%. 2. Severity of condition on admission. Sixty-two per cent of the patients admitted with tuberculous meningitis in an advanced stage recovered; also 86.5% of those with the disease in an intermediate stage, and 98% of those in the initial stage. 3. Previous inadequate treatment before hospitalization. Miliary tuberculosis did not constitute an aggravating factor. The rate of mortality from tuberculous meningitis declined between 1953 and 1956. Eleven patients with severe form of the disease suffered purulent meningitis; 9 of them died. Eight patients who had been dismissed too early on account of a normal blood picture suffered relapse. Late neurological, psychic, and endocrinal complications occurred in 59 patients, but a decline in the incidence of sequelae was noticed in the last 3 years of observation.

Occurrence of Pseudotumor Cerebri (Benign Intracranial Hypertension) During Treatment of Children With Asthma by Adrenal Steroids: Report of Three Cases. S. C. Dees and H. W. McKay, Jr. Pediatrics 23:1143-1151 (June) 1959 [Springfield, Ill.].

Pseudotumor cerebri is a relatively rare condition, particularly in children, and has not been reported in patients receiving adrenal steroid therapy. This prompted the authors to report the history of 3 boys, aged 4, 5, and 6 years, who were admitted to Duke University Medical Center, Durham, N. C., and in whom pseudotumor cerebri developed during a period when the dosage of steroid was being decreased to low levels. The boys had received continuous steroid treatment for several years, beginning in late infancy. They presented the following symptoms at the time of admittance: severe headache, anorexia, nausea, intractable projectile vomiting, diplopia, and neurological signs, including paresthesia, weakness, ataxia, and dysarthria. Characteristic physical findings were papilledema, cranial nerve palsies, normal blood pressure, very short stature, obesity, and "moon" facies. The cerebrospinal fluid was under greatly increased pressure but was otherwise normal, and the ventricular systems were small but normally situated. The boys had acquired the appearance of pituitary basophilism (Cushing's disease).

The mechanism by which pseudotumor cerebri developed in these 3 children could not be determined. No evidence for an acute allergic reaction in the central nervous system could be found, nor did hypoxia seem to be a cause for pseudotumor cerebri, because both previous and subsequent attacks of asthma had not reproduced signs of the condition. All the children had always had relatively high concentrations of hemoglobin regardless of the degree of asthma. There was no significant dehydration, and fluid therapy quickly restored the mild electrolyte changes to normal. Intensive investigations failed to clarify the etiology of pseudotumor cerebri. The considerations discussed by the authors lead to the assumption that it may be an unusual reaction to long-term steroid therapy or to withdrawal of steroids after prolonged use. It is believed that some form of adrenocorticosteroid insufficiency may have been involved in the development of this condition.

Kwashiorkor, as Seen by the Practitioner (Based upon 55 Clinical Observations). A. Bezon. Presse méd. 67:932-934 (May 9) 1959 (In French) [Paris].

The study of 55 cases of African kwashiorkor enabled the author to draw conclusions about the etiological and clinical aspects of this disease. Late weaning and psychological upsets can play a part in the etiology of this disease, as may be seen by the example of a 15-month-old boy whose illness began upon weaning and separation from his family. The disease has a lower mortality when it occurs in children more than 3 years old. It occurs in boys more frequently than in girls, but it has an identical course. In this series, 1 out of 3 patients had a disease during the days or weeks preceding the occurrence of kwashiorkor. In 33% of these instances with a disease antecedent, the disease was measles. There was a curious absence of malaria symptoms. Clinically, epithelial symptomatology is the only nonequivocal type of indication. Three types of skin modifications are: (1) keratosic (hyperkeratosis, ulcerative or desquamative keratolysis), (2) decoloration or hyperpigmentation, and (3) sudoral disorder, which to the author's knowledge has not yet been noted by other investigators. This author believes that an indication of kwashiorkor may be a lack of perspiration on the face at mealtime; normal perspiration at meals may be a criterion of cure. Edema is one of the principal symptoms of kwashiorkor. There is an interstitial water retention which initiates the serious stage of the disease. Edema disappears, but may be replaced by a clinical dehydration with a grave prognosis. Sometimes at the beginning of developing malnutrition, there is a balance between ordinary episodic diarrhea and the appearance of edema. Other associated syndromes are (1) diarrhea, anorexia, and dehydration and (2) drying of the edema with hyperpigmentation and hyperkeratosis.

The ideal therapeutic agent would bring a balance between water loss and the reestablishment of anabolism. All too often disappearance of edema is followed by dehydration and weight loss. Corrective treatment of the hydration disorder leads from one extreme to the other, and yet the cellular processes of metabolic exchange are not restored. There are 3 stages of kwashiorkor: (1) reversible malnutrition, (2) progressive edematous malnutrition with decoloration, and (3) drying kwashiorkor with hyperkeratosis and hyperpigmentation. In this disease opposing processes succeed each other, and the practitioner in tropical regions is at a therapeutic impasse.

Frequency and Diagnostic Importance of the So-called "Minor" Manifestations of Rheumatic Disease in Children: A Clinical and Statistical Study of 206 Cases Observed at the Clinica Pediatrica of Florence, Italy, from 1947 to 1957. F. Ragazzini and S. Mori. Riv. clin. pediat. 61:105-125 (Aug.) 1958 (In Italian) [Florence, Italy].

Late or wrong diagnosis in children with rheumatic disease characterized by an atypical onset is still frequent despite the emphasis in the literature on the multiform manifestations of this disease. The authors report on 206 children (108 boys and 98 girls) who suffered from rheumatic disease for the first time and who were observed at the Clinica Pediatrica of Florence between 1947 and 1957. Most of the children (157) were between 6 and 11 years of age; only 36 were between 3 and 5 years of age. Morbidity was most frequent during the months of September (with 20 cases), October (with 25), and November (with 23) and was least frequent in August (with 12 cases). The family histories showed that rheumatic disease had been present in the parents of 12 children (5.8%) and in the brothers or sisters of 3 (1.4%); tuberculosis had afflicted members of the families of 11.7% of the children.

During the 12 months before manifestation of rheumatic disease, 48 children had suffered from sore throat, 13 had a disease of the respiratory tract, 7 had light fever, anorexia, or anemia, 5 had tuberculosis, 2 had scarlet fever, and 1 had a surgical trauma. The onset of the rheumatic disease was atypical in 49 children; 22 of them had painful abdominal symptoms, and because of these symptoms there was generally suspected a condition, such as appendicitis, requiring surgery. Fever, however, had preceded the abdominal pain, and vomiting was rare or absent. Fever was the first symptom in 21 of the 49 atypical cases, and in some children it was associated with sore throat. The authors stress the importance of a "precautionary" antirheumatic treatment in children who present fever and an undecided clinical picture and in whom an atypical rheumatic disease is suspected.

Primary Aldosteronism in a 9-Year-Old Child. N. Kretchmer, A. Dickinson, H. McNamara and R. Karl. Pediatrics 23:1115-1124 (June) 1959 [Springfield, Ill.].

The authors present the history of a 9-year-old boy with primary aldosteronism resulting from bilateral adrenal hyperplasia. The patient, a well-developed, well-nourished, prepubescent boy, was admitted to the New York Hospital-Cornell Medical Center in October, 1956, for evaluation of hypertension. Blood pressure in both upper and lower extremities was 200/150 mm. Hg. Polydipsia and polyuria were also present. The patient had a persistent hypokalemia and an elevated carbon dioxide content in the serum, although the pH was within normal limits. These findings were consistent with a diagnosis of primary aldosteronism. Aldosterone excretion in the urine was found to be significantly elevated above the normal values, whereas the values for 17-ketosteroids and 17-hydroxysteroids were normal. The patient was placed on a controlled sodium and potassium intake, and a daily balance of these electrolytes was determined. Four days after the diet was instituted, he was given 25 mg. of cortisone every 12 hours, which caused an increased negative potassium balance and, paradoxically, a negative sodium balance. The negative balance resulted from increased urinary excretion of both ions.

The diagnosis of primary aldosteronism was sufficiently established, and transabdominal adrenal exploration was performed in December, 1956. The left adrenal gland was larger and grossly more abnormal and was removed in entirety. Histological examination of the left adrenal gland showed hyperplasia of the zona fasciculata. A biopsy specimen taken from the left renal cortex showed evidence of an inflammatory process and some fibrosis. Pathological diagnosis was chronic pyelonephritis. The patient's preoperative status had not changed except for a mild decrease in polyuria and polydipsia, but urinary excretion of aldosterone, although decreased, was still elevated above normal. All the evidence indicated that the patient had bilateral adrenal hyperplasia. After considerable deliberation a subtotal adrenalectomy was performed. The immediate postoperative course was complicated by an elevation of blood pressure and by a diuresis for the first 72 hours. Thereafter both decreased to normal values. Maintenance adrenal steroid therapy, initiated just prior to surgery, was discontinued on the 5th day after operation, and the patient was fully ambulatory by the 8th postoperative day.

The patient was discharged from the hospital toward the end of March, 1957, with an average blood pressure of 135/90 mm. Hg. Most of the laboratory data were within normal ranges, but renal function had not improved since the preoperative evaluation. Because only a subtotal adrenalectomy was performed, the patient has been leading a completely normal life; he has not needed any medication and has been free of the dangers attendant to adrenal insufficiency. From all the evidence presented, it is reasonable to conclude that there had been hypersecretion of aldosterone by the adrenal glands of this boy since early infancy. Primary aldosteronism should be considered in every child admitted to the hospital with a diagnosis of essential hypertension, inasmuch as the latter condition when due to primary aldosteronism is a curable disease.

Aldosteronism and Hypertension: The Influence of Complete Adrenalectomy Upon Essential Hypertension in a Child. R. J. Slater, D. W. Geiger, J. Leeson and A. G. Gornall. Pediatrics 23:1125-1135 (June) 1959 [Springfield, Ill.].

The favorable influence of complete adrenalectomy on a 5-year-old boy with severe essential hypertension and cardiac failure is described by the authors. Repeated investigations failed to clarify the etiology of the hypertension. After extensive trials of medical management, including low intake of salt and administration of hypotensive drugs, only a moderate decrease in blood pressure was achieved, and the clinical response was unsatisfactory. Since increased excretion of aldosterone and a sensitive hypotensive response to salt restriction implicated disordered adrenal function, a two-stage adrenalectomy was done. The final achievement has been a marked improvement in cardiovascular status and reversal of impaired renal clearances. The condition of the boy has been maintained with cortisone and 9-alpha-fluorohydrocortisone. Despite these preliminary favorable results, emphasis is directed to the extreme caution which must attend the decision to undertake such a procedure.

Ceroid Storage Disease in Childhood. E. H. Oppenheimer and E. C. Andrews, Jr. Pediatrics 23:1091-1102 (June) 1959 [Springfield, Ill.].

The authors report the history of a 4-year-old boy and a 2-year-old girl, in both of whom the intracellular material found in the tissues at autopsy fulfills the present histochemical criteria for ceroid storage. In both patients there was a long history of nutritional disturbance; the children had developed poorly, and the girl presented severe mental retardation. The boy demonstrated a history of rickets, but demineralization of the bones was noted one year before death. Examination at autopsy revealed that the ribs were greatly distorted by both scurvy and rickets. Probable metastatic calcification was also noted in an artery adjacent to the thymus. Biopsy of the liver at 3 years of age revealed early cirrhosis with slight deposition of ceroid in the scars. There was a history of transfusions at one year of age, presenting an opportunity for the development of serum hepatitis, but there was no widespread loss of liver parenchyma in the biopsy section, such as is seen with characteristic postnecrotic cirrhosis. Autopsy revealed a progressed cirrhosis associated with greater numbers of ceroid-containing macrophages and central necrosis. The autopsy findings indicated that death was due to hepatic insufficiency with jaundice, ascites, edema, gynecomastia, and purpura, in addition to a marked electrolyte disturbance after protracted diarrhea.

Although the immediate cause of death in the girl was pneumonia, there was marked malnutrition and early cirrhosis of the liver. Ceroid was found mostly in macrophages in the cirrhotic liver. Jaundice occurred at the age of one month, which may have contributed to the production of the cirrhosis. No evidence of avitaminosis—no rickets, scurvy, or indication of deficiency of vitamin A or vitamin E—was found at autopsy, nor was any lipid found in the liver parenchyma, which could be attributed to a disorder of liver metabolism. Mental retardation was noted clinically, but no pathological changes could be recognized in the central nervous system. Although ceroid was present in macrophages in both of these cases, there is not enough evidence to indicate that it represented the same disease entity. In the boy the storage of ceroid appeared to be "primary," although associated with severe nutritional disturbance, whereas in the girl the presence of ceroid-containing macrophages in scar tissue might well have been a minor secondary finding in association with the cirrhosis.

DERMATOLOGY

Extensive Tuberculous Lupus After BCG Vaccination. S. Boulle, J. Civatte and M. Boulle. Presse méd. 67:606-609. (March 25) 1959 (In French) [Paris].

A report is given of an extensive tuberculous lupus which developed on a child's shoulder after BCG vaccination by scarifications on the same site. There was also a fistulous adenopathy of the left armpit. Arguments based on histological study are given; these are in favor of the tuberculous nature and BCG origin of the lupus. Emphasis has been put on the particular virulence of the vaccine and on a previously unknown allergic sensitivity to tuberculosis. In this patient the skin became progressively sensitized during development of the true inoculation lesion produced by the vaccine. The contact of BCG with this skin, or with allergic skin, gave rise to lupus transformation of the inoculated tissues. This rare outcome is a particular etiological form of the relatively common development of the spontaneous inoculation lesion of Koch's bacillus. In the patient described, lupus was observed at the age of 4 years in the region where BCG vaccination was performed at the age of 7 months.

Calcinosis in Dermatomyositis: Observations on Course of Disease in Children and Adults. S. A. Muller, R. K. Winkelmann and L. A. Brunsting. A. M. A. Arch. Dermat. 79:669-673 (June) 1959 [Chicago].

The records of 118 patients with dermatomyositis, who were seen at the Mayo Clinic from 1945 to 1955, were reviewed in an effort to determine the significance of calcinosis in dermatomyositis and to contrast its pattern of occurrence with that in scleroderma. Of the 118 patients, 87 were adults and 31 were children. The youngest patient was 18 months old, and the oldest was 71 years. The ratio of females to males was 3 to 1. All the patients were followed up for a minimum of one year. Among the 87 adult patients, 12 had calcinosis and 75 did not, while 17 of the 31 children had calcinosis and 14 were without calcinosis. Calcinosis was usually seen centered in the proximal muscles of the shoulder and pelvic girdles. All but 3 of the patients with calcinosis were females. This greatly increased incidence of calcinosis in females was similarly observed in patients with scleroderma. In several patients the amount of calcium increased steadily, usually over several months; thereafter no apparent increase occurred.

Episodes of ulceration with extrusion of calcified debris occurred periodically in several instances, particularly in children. Ulcerations were frequently associated with cellulitis and a severe systemic reaction. Episodes of extrusion of calcified debris occasionally were confused with exacerbations of the disease. Healing usually occurred spontaneously, but surgical removal of the calcified debris was sometimes necessary. In only one patient was the degree of calcinosis seen to decrease significantly after such episodes. Of the 29 patients with calcinosis, one patient, a child, died. Of the 89 patients without calcinosis, 33 died. This suggests that the occurrence of calcinosis is a good prognostic sign of survival.

Calcinosis did not develop among those who were less seriously affected and who had less severe disabilities. Of 11 adults who recovered completely, none had calcinosis. It should be emphasized that in the acute phase of the disease it is impossible to predict the course of the disease or the final extent of muscle involvement. Recurrent episodes of ulceration are a frequent manifestation of calcinosis in dermatomyositis and occur most commonly in the buttocks and the thighs. The pattern, course, and associated prognosis of calcinosis in dermatomyositis differ distinctly from those of calcinosis in scleroderma.

Eczema and Psoriasis Through Sensitization to Air-borne Allergens. E. Henocq and L. Guibert. Semaine hôp. Paris 35:1568-1570 (May 4) 1959 (In French) [Paris].

The allergic origin of eczema, whether the disease is the true or so-called diathetic eczema or a dermatitis due to an external cause, is generally admitted. The allergen responsible for diathetic eczema is often hard to identify. This form of eczema, which occurs in persons with hereditary allergic antecedents and which may begin in infancy, is often accompanied or followed by asthma or hay fever. Searching inquiry will usually reveal the rhythm of the attacks, the influence of the seasons, and the nature of the patient's living conditions, and may lead to the incrimination of bedding material, fungi. house dust, or the presence of an animal (dog or cat) in the house. Desensitization treatment often produces very favorable results in eczemas of this kind, in both children and adults.

Certain cases of eczema, apart from diathetic eczema and contact dermatitis, may be due to airborne allergens. This was illustrated in a patient in whom eczema of the hands appeared within 24 hours after she handled cultures of Mucor. Intradermal tests revealed elective sensitivity to this fungus, and specific desensitization treatment resulted in a rapid cure. Subsequent attacks due to Mucor and, eventually, to other fungi were relieved by further treatment, and specific desensitization to all the offending organisms put a stop to any new clinical manifestations.

The part played by air-borne allergens in the causation of certain eczemas, together with various other considerations, led the authors to investigate the possibility of an allergic origin for psoriasis. The results proved conclusively that many patients with psoriasis react favorably to specific desensitization to these allergens. Patients with psoriasis usually have a certain neurovegetative instability, sometimes even presenting forms of anxiety, obsession, or depression, so that the disease is often called psychosomatic. It is, of course, difficult to decide whether the psychological disturbances of the psoriatic patient are the result of his skin disease or its determining cause. Asthma, too, often has a psychosomatic component, but no one underestimates the importance of the allergic factor in its causation or denies that patients with asthma may be helped by specific desensitization treatment.

Allergy probably does not provide a complete explanation for psoriasis, but the proportion of patients in the authors' series of 60 whose condition has been cured or improved is too large for coincidence. More than 50 instances of sensitivity to air-borne allergens (of which fungi and dust were the most frequent) were found in the 60 patients, and interrogation revealed that familial or personal allergic antecedents were present in 40% of the 60. Patients with psoriasis should be systematically investigated for allergy, and those with positive skin reactions should be given specific desensitization treatment before any other therapy is tried.

An Evaluation of a New Cerumenolytic Agent. J. Q. Gant Jr. A. M. A. Arch. Dermat. 79:651-653 (June) 1959 [Chicago].

The author reports on 163 patients (children and adults) with excessive deposits of earwax who were treated with Cerumenex (triethanolamine polypeptide oleate-condensate in propylene glycol with chlorobutanol), a new ceruminolytic agent. In 87.1% of the patients there was superior removal of the earwax; in 11.0% there was satisfactory removal; and in only 1.9% was there failure to improve the condition. There were no untoward side-effects noted in any patients. Ten patients tested for sensitivity over a period of 6 weeks showed no sign of irritation or allergic reaction. The results of this clinical study show that Cerumene is an unusually effective and safe ceruminolytic agent.

Smoking, Necrobiosis Lipoidica, Granulomatosis Disciformis Chronica Progressiva. E. J. Ringrose. A. M. A. Arch. Dermat. 79:635-640 (June) 1959 [Chicago].

The author presents the history of 7 women, their ages ranging from 24 to 64 years, who had necrobiosis lipoidica diabeticorum and granulomatosis disciformis chronica progressiva, which are one and the same condition. Six patients were nondiabetics, and one was a diabetic. All the patients revealed a long history of smoking and thus presented a common causative factor. This factor is believed to be responsible for the development of necrobiosis lipoidica diabeticorum, since histopathological changes seen in the tissue excised from lesions in these patients were explained on the basis of a chronic recurring ischemia of the vessel walls. Smoking subjects the person to the influence of nicotine which causes his blood vessels to undergo intermittent spasms and results in intermittent ischemia of the vessel walls themselves and of the tissues supplied by these vessels. This leads first to intimal swelling and subsequently to damage to all layers of the vessel. It appears that smoking of only a few cigarettes a day might be of considerable importance in persons who have high-grade constitutional or other vascular defects. Smoking is believed to aggravate necrobiosis lipoidica diabeticorum. It is suggested that smoking be strongly considered in the search for causative factors in disorders of unknown etiology in which vascular disturbances may play an important part.

UROLOGY

Adrenal Cysts: Review of the Literature and Report of Three Cases. G. A. Abeshouse, R. B. Goldstein and B. S. Abeshouse. J. Urol. 81:711-719 (June) 1959 [Baltimore].

The authors report on a 3-year-old boy and on 2 women, aged 19 and 42 years, with adrenal cysts for which the patients were operated on. Pathological examination of the operative specimen of the boy revealed a hemorrhagic cyst of adrenal origin, which contained old coagulated blood and serum with blood pigment adherent to the inner surface of the cyst wall. The cystic mass was removed with the right kidney to which it adhered. The adrenal cyst of the younger woman was of lymphangiomatous origin. A small portion of the left adrenal was removed with the cyst. Calcification was present in the walls of the cyst. Examination of the operative specimen of the second woman revealed a solitary serous cyst of the right adrenal gland of lymphatic origin. The contents of the cyst were composed of a thick, clear, gelatinous fluid. Recovery was uneventful in all 3 patients.

One hundred fifty-two cases of adrenal cysts were collected from the literature. The diagnosis was established by autopsy in 88 and by surgical intervention in 64. Adrenal cysts are rare clinical and pathological lesions which may occur at any age but are more commonly observed in patients in the 5th and 6th decades. They are observed more commonly in female than in male patients in the ratio of 3 to 1. Adrenal cysts are usually unilateral and show no special predilection for either kidney. The commonest variety of adrenal cyst is the pseudocyst which may originate in a hematoma in or around the adrenal or in an area of hemorrhage and necrosis within a benign or malignant adrenal tumor. The second commonest variety is the lymphangiomatosus (serous) cyst resulting from lymphangiectasis. Many adrenal cysts are asymptomatic and are accidental findings at autopsy. The most prominent clinical features are dull pain in the adrenal area, gastrointestinal symptoms, and a palpable mass.

The diagnosis is usually made in suspected cases by properly selected roentgenologic studies, which include plain and lateral roentgenograms, excretory urography, retrograde pyelography, tomography, retroperitoneal air injection, and gastrointestinal studies. The presence of calcification in a cystic mass above the kidney is strongly suggestive of an adrenal cyst. The operation of choice is excision of the cyst with preservation of the ipsilateral kidney. The operative approach may be transperitoneal, lumbar (plain, excision of one or more ribs), or transthoracic.

Treatment of Peyronie's Disease with Potassium Para-Aminobenzoate (Potaba). C. J. D. Zarafonetis and T. M. Horrax. J. Urol. 81:770-772 (June) 1959 [Baltimore].

The authors report on 21 men, between the ages of 31 and 62 years, with induration of corpora cavernosa (Peyronie's disease), who were treated with potassium para-aminobenzoate (Potaba) administered orally in doses of 12 Gm. daily, divided into 6 doses of 2 Gm. each or into 4 doses of 3 Gm. each. The drug was usually given in the form of a chilled 10% aqueous solution or in 0.5-Gm. capsules. Treatment was continued for periods ranging from 3 months to 2 years. Before the institution of treatment, 16 of the 21 patients had pain upon erection. After treatment with Potaba, all reported that the pain disappeared completely. This was the earliest change to be noted, usually occurring within a few weeks after institution of the therapy. Marked penile deformity, that is deviation laterally or dorsally, or both, was present in 17 patients. After treatment, the deformity disappeared in 3, and 11 noted definite straightening of the penis on erection. A well-defined Peyronie's plaque was present in all 21 patients. With Potaba therapy it was observed that the plaque disappeared in 2 patients, diminished in size in 14, and so far remained unchanged in 5. Seven patients have now been off therapy for 6 to 12 months, and as yet have reported no recurrence of symptoms. The remaining patients are still on the treatment regimen. The reported observations appear to warrant further use of Potaba in the management of induration of corpora cavernosa.

Aerobacter Aerogenes Bacteremia and Bacilluria. H. Seneca. Surg. Gynec. & Obst. 108:733-739 (June) 1959 [Chicago].

The author cites reports indicating a striking increase in the frequency of Aerobacter aerogenes in urinary tract infections. Because of marked differences in resistance to treatment employing chemotherapeutic agents, it has become imperative to differentiate between infecting coliform organisms of the Escherichia coli and A. aerogenes groups early in treatment. Among 108 cases of bacilluria due to A. aerogenes, drug susceptibility studies indicated that A. aerogenes is a highly resistant organism, and that infections with this organism are very resistant to chemotherapy. The drug of choice is most often chloramphenicol or sulfadiazine; second choice is penicillin plus streptomycin or tetracycline; as a third choice, Gantrisin is employed. An occasional organism may be sensitive to Furadantin, erythromycin, or Matromycin.

During the 5-year period from 1952 to 1957, 10 cases of bacteremia due to A. aerogenes occurred among 74 cases of gram-negative rod bacteremias at the Columbia-Presbyterian Medical Center, New York. Four patients with A. aerogenes bacteremia recovered; 6 deaths occurred during the period between 1954 and 1957. Eight of 9 patients had had surgical intervention prior to bacteremia; in one case it was a terminal medical complication. No universally effective chemotherapeutic program was observed. The final clinical picture was one of renal failure.

Dysgenetic Gonadomas and Other Gonadal Neoplasms in Intersexes: Report of 5 Cases and Review of the Literature. M. M. Melicow and A. C. Uson. Cancer 12:552-572 (May-June) 1959 [Philadelphia].

The authors obtained from the files of the Squier urologic clinic of the Columbia-Presbyterian Medical Center, New York, the histories of 5 patients with somatosexual ambiguities, who had dysgenetic gonadal neoplasms. Reviewing the literature on the subject, they found that, to date, about 140 case reports of gonadal tumors in intersexes have been published. They feel that the incidence of such an association is probably greater than this number would indicate, and they list factors that might explain why more cases have not been reported.

From the cases presented and from the literature, the authors gained the impression that in patients with congenital somatosexual ambiguities there exists a tendency for the development of gonadal neoplasms. For this reason, it is desirable for such individuals to be examined before puberty, so that adequate biopsy specimens of their gonads can be obtained. These dysgenetic gonads may not be enlarged and yet may already be the seat of tumor. For these reasons, prophylactic or elective gonadectomy should be performed, when the patient reaches puberty. Children with the adrenogenital syndrome should be excluded from this procedure. An abdominal mass in any patient with a somatosexual ambiguity should suggest a gonadal neoplasm until proved otherwise. An acute condition within the abdomen in such patients should be interpreted as being the result of the twist of the pedicle of the gonadal growth.

The management of intersexes with gonadal tumors depends on the following conditions: pathological type and developmental stage of the underlying "growth," appearance of the external genitals, age and sex according to which the patient was reared, and presenting clinical syndrome (acute condition within the abdomen, sterility, inguinal hernia, etc.). It is hoped that awareness on the part of physicians as to the frequent association of neoplasms in dysgenetic gonads, and as to the importance of the use of newer diagnostic procedures (such as chromatin sex pattern determinations, hormonal bioassays, etc.), will result in achieving accurate diagnosis of "dysgenetic gonadomas" at an early stage of development. It would then be possible to accumulate sufficient data, which should aid in understanding the pathological nature of, and in arriving at a proper classification for, this bizarre group of gonadal tumors in intersexes.

Carcinoma of the Bladder: Sites of Metastases. T. R. Fetter, J. H. Bogaev, B. McCuskey and J. L. Seres. J. Urol. 81:746-748 (June) 1959 [Baltimore].

The authors present an analysis of 637 patients, between the ages of 20 and 93 years, who were admitted to the Jefferson Medical College Hospital in Philadelphia between January, 1940, and December, 1957, and in whom carcinoma of the bladder was found by surgical pathological study. Of the 637 patients, 490 (77%) were men, and 147 (23%) were women. The incidence of carcinoma of the bladder was highest among those between the ages of 61 and 70 years. In 55 consecutive postmortem examination carried out during the same period on patients with carcinoma of the bladder, metastases were noted in 39, an incidence of 71%. The lymph nodes were the most frequent site of metastasis. The lungs were the most commonly involved parenchymal structures. Metastasis to bone occurred in 37% of the cases, metastasis to the liver in 13%, and metastasis to the adrenal in 12%. This tendency to widespread metastasis requires diligent examination before undertaking extensive surgical procedures in the management of patients with carcinoma of the bladder. The age and sex distribution among the patients studied correlated well with other reports in the literature.

THERAPEUTICS

Salicylate Intoxication with Special Reference to the Development of Hypokalemia. E. D. Robin, R. P. Davis and S. B. Rees. Am. J. Med. 26:869-882 (June) 1959 [New York].

The authors report the case histories of 6 female patients, between the ages of 5 and 52 years, with severe salicylate intoxication, and they discuss the features of this disorder in the light of these cases. The intoxication resulted from the ingestion of about 25 to 50 Gm. of aspirin. The initial effect of salicylates on acid-base balance is the production of respiratory alkalosis. The respiratory alkalosis is due to a direct central effect of the salicylate, the ability of which to produce hyperventilation appears to be mediated by the anterior hypothalamus. One of the important results of this respiratory alkalosis is hypopotassemia. The latter is manifested by low serum potassium concentrations and electrocardiographic and neuromuscular changes. The persistence of hypopotassemia when alkalosis is no longer present indicates that potassium depletion is likewise present. The manifestations of hypopotassemia and potassium depletion may be reversed by adequate potassium therapy. Other consequences of the respiratory alkalosis may include tetany and interference with tissue oxygenation. Therapy for this phase of the disease consists of fluid replacement, potassium replacement, and administration of oxygen. The use of alkali and of respiratory center depressants is contraindicated.

In some patients with severe salicylate intoxication, metabolic acidosis may develop after the stage of respiratory alkalosis. The manifestations of the respiratory alkalosis and metabolic acidosis are so similar that frequent blood pH measurements are necessary to guide the therapy. This is particularly true because the disease may progress from one stage to the other without obvious change in the patient's status. The most important therapeutic agent for metabolic acidosis is the administration of sodium bicarbonate or lactate. Other important effects of salicylate intoxication include fever, hypoprothrombinemia, hemorrhagic gastritis, hypermetabolism, hypouricemia, renal failure, delirium, coma, and ultimately depression of the central nervous system. The prognosis of the adequately treated patient would appear to be good.

PATHOLOGY

Nonspecific Reactive Hepatitis in Aged and Infirm People. F. Schaffner and H. Popper. Am. J. Digest. Dis. 4:389-399 (May) 1959 [New York].

Liver biopsies were performed with a Terry aspiration biopsy needle on 94 persons who were patients in a county infirmary. None of these patients had any known hepatic or gastrointestinal disorder, and none had recently been given any drug known to cause hepatic injury. Their ages ranged from 35 to 92 years, with an average age of 63.9 years. The diagnosis in 73 of the 94 patients was either arteriosclerotic or hypertensive cardiovascular disease; of the remaining 21 patients, 12 had chronic bone or joint disorders, and 9 had various neurological disorders. Nonspecific reactive hepatitis in the 94 patients was characterized by a group of abnormal histological findings, including duct proliferation, portal and periportal inflammatory infiltration, focal necrosis, Kupffer-cell mobilization, and evidence of regeneration. No correlation with results of hepatic tests could be obtained, and these results were sometimes abnormal without any apparent reason. The use of such a group of patients for various studies in which hepatic structural and functional integrity is of importance must be preceded by control liver biopsies and by repeated and careful evaluation of hepatic function.

RADIOLOGY

The Volume of the Heart in Essential Hypertension: A Radiologic Study. S. Panichi, G. Muiesan and I. Bonechi. Minerva med. 50:1369-1373 (May 5) 1959 (In Italian) [Turin, Italy].

The volume of the heart was measured in 2 groups of patients with essential hypertension. The first group was composed of 50 women, 39 to 75 years of age. The volume of the heart was normal in 16 of these patients, slightly above normal in 21, and highly above normal in 10; the remaining 3 patients presented a marked cardiomegaly. All the patients with a volume of the heart above 600 cc. per square meter of body surface had had hypertension for more than 5 years; the patients with a volume of from 500 to 600 cc. per square meter had had hypertension for from 3 to 10 years; the remaining patients had had hypertension for from a few months to a few years. The second group was composed of 50 men, 36 to 72 years of age. The volume of the heart was normal in 15 of these patients, slightly above normal in 22, and highly above normal in 12; only one patient who had had hypertension for more than 10 years presented a marked cardiomegaly. Three patients who had suffered hypertension for 10 years or more presented values in which the volume of the heart was below 500 cc. per square meter of body surface.

The authors believe that an increase in the volume of the heart may be of help in determining the extent of the functional involvement of the heart. A comparison of the radiologic findings with the clinical, electrocardiographic, and blood findings showed that patients with values of the volume of the heart above normal presented only a simple hypertrophy of the left ventricle and that patients with values of the volume of the heart between 500 and 600 cc. per square meter presented a hypertrophy of the left ventricle combined with some dilatation of the heart, while patients with values above 600 cc. per square meter presented a ventricular hypertrophy with dilatation of the heart. The volume of the heart was normal in 31 patients, but the averages of the values present in these patients (402 cc. per square meter of body surface for the men and 394 cc. per square meter for the women) were higher than the normal averages which were, respectively, 374 and 356 cc. per square meter. The authors believe that some involvement of the heart, not otherwise ascertainable, was already present in these patients.

Mass Radiography and Cancer of the Lung. E. Posner, L. A. McDowell and K. W. Cross. Brit. M. J. 1:1213-1218 (May 9) 1959 [London].

During 1955, the last year for which national figures have been published, mass radiography units in England and Wales detected 1,482 cases of cancer of the lung and mediastinum. National morbidity figures for new cases of cancer of the lung are not available, but the 17,272 deaths from cancer of the lung during 1955 suggest that at present mass radiography does not find more than 10% of all new cases of cancer of the lung. Almost half of the above number were not detected by routine mass radiography, but at sessions for symptomatic cases referred by general practitioners, a type of service now widely employed by many such units. The authors review observations on 238 male patients in whom cancer of the lung was found by 6 mass radiography units of the Birmingham Regional Hospital Board in the 12 months following July 1, 1955, and whose fate had been traced by the Regional Cancer Registry after 12 months. In this report they are concerned chiefly with the comparison of the resectability rates among patients with lung cancers found by conventional routine mass radiography and among patients referred to the units by general practitioners.

The authors did not obtain a clear-cut answer to the question of the value of mass radiography in the detection of lung cancer. They are also aware that a follow-up period of 12 months is short, but the investigation is continuing. They found a higher resectability rate in cases found at routine surveys as compared with cases referred by general practitioners because of symptoms. The difference, however, was small and not statistically significant. In a number of cases the fate of the patient was governed by factors of age, histology, acceptance, or refusal of operation—factors which are little, or not at all, related to early diagnosis. The 12-month survival rate, irrespective of treatment, was higher for routine-survey patients than for general-practitioner patients. Lobectomy was performed on a larger proportion of patients with cancers detected by routine survey than on those referred by practitioners. Patients with symptoms were referred by general practitioners generally without undue delay, and the majority of resections were carried out within the first 2 months after x-ray examination. The small number of truly asymptomatic cases and the absence of small peripheral shadows in this series are discussed in their relation to future mass radiography policy. The installation of more 100-mm. x-ray units to deal with a larger number of general-practitioner referrals, particularly men in the critical age groups, is suggested.

Extensive Lumbar Meningocele Associated with Neurofibromatosis. B. P. Sammons and D. F. Thomas. Am. J. Roentgenol. 81:1021-1025 (June) 1959 [Springfield, Ill.].

The authors report a case of meningocele in the lumbar spine associated with neurofibromatosis in a 27-year-old sailor who was admitted to the United States Naval Hospital in St. Albans, N. Y., complaining of low-back pain of 10 days' duration. There was no history of any familial disease. Physical examination revealed numerous fine cutaneous nodules and small pigmented areas. Several soft nodules (1 to 2 cm. in size; molluscum fibrosum) were noted on the trunk and forehead. The results of the neurological examination were within normal limits. Hemogram, urinalysis, and spinal fluid chemistries and pressures were normal. Roentgenograms of the lumbosacral spine revealed deep scalloping of the posterior portion of the bodies of the 11th thoracic to the 4th lumbar vertebrae and marked thinning of the pedicles throughout this area. Iophendylate myelograms showed herniation of the meninges outside the confines of the vertebral canal. An intravenous pyelogram revealed lateral displacement and scalloping of the right ureter below the renal pelvis. The right ureter near the pelvis brim was displaced medially, and roentgenographic studies of the small intestine showed a *persistent extrinsic pressure defect on the ileum;* these changes were probably due to retroperitoneal and visceral neurofibromas respectively.

Twenty-nine cases of intrathoracic meningocele associated with neurofibromatosis were collected from the literature, but none was reported before in the lumbar spine and primarily intravertebral in location. A mesodermal origin for the combination of meningocele and neurofibromatosis has been suggested by the occurrence of thoracic meningoceles with neurofibromatosis. The case of the sailor with lumbar meningocele associated with neurofibromatosis further supports the concept of a lack of specificity for the thoracic spine.

BIOCHEMISTRY

Possible Sites of Macroglobulin Synthesis: A Study Made with Fluorescent Antibody. C. C. Curtain and J. F. O'Dea. Australasian Ann. Med. 8:143-150 (May) 1959 [Sydney, Australia].

According to the authors, it was Waldenström who in 1948 first used the term "macroglobulin" to describe proteins in human serum having molecular weights of over 1 million. In his cases these proteins were associated with a clinical syndrome characterized by lethargy, bleeding tendency, hemorrhagic purpura, and enlargement of the liver, spleen, and lymph nodes. In smaller amounts, macroglobulins have been found associated with lymphosarcoma and, very rarely, with myeloma. This paper describes experiments on the localization of macroglobulins by the fluorescent antibody technique in the tissues of 2 patients, one showing Mikulicz's syndrome (chronic enlargement of the lacrimal and salivary glands) and the other having myeloma. The serums of both patients contained considerable amounts of macroglobulin, although neither showed the clinical signs associated with macroglobulinemia of Waldenström.

The first patient had macroglobulin in large quantities in mature and immature plasma cells in the bone marrow. It was considered that the macroglobulin was the product of a plasmacytosis reactive to the pathological process in the patient's parotid gland. The second patient had both a macroglobulin and a myeloma globulin in his serum. The fluorescent antibody studies suggested that these 2 abnormal proteins originated in different plasma cells in the bone marrow, which were, however, morphologically identical with orthodox staining. Neither protein could be demonstrated in frozen sections of other tissues obtained at autopsy.

Zinc Metabolism in Hepatic Dysfunction. B. L. Vallee, W. E. C. Wacker, A. F. Bartholomay and F. L. Hoch. Ann. Int. Med. 50:1077-1091 (May) 1959 [Lancaster, Pa.].

Recent investigations have demonstrated the presence of zinc in several dehydrogenases and in pancreatic carboxypeptidase. Two of these enzymes, alcohol dehydrogenase and glutamic dehydrogenase, are isolated from mammalian liver. Zinc is an active enzymatic site in these enzymes, and its presence is indispensable to their activity. Zinc is thus involved in the oxidation of ethanol, a substance that is considered to have a primary role in the development of some forms of Laennec's cirrhosis, and in the faulty metabolism of ammonia in patients with cirrhosis. These circumstances suggested an investigation of the metabolism of this metal in patients with liver disease. For the description of procedures for the analysis of zinc and the cleaning of glassware and containers the authors refer to earlier reports. De-ionized water was used throughout. Duplicate zinc analyses were performed on serum from venous blood, obtained from normal persons and from patients (both male and female) with Laennec's cirrhosis. Zinc was extracted also from 24-hour urine specimens of normal men and of men with postalcoholic cirrhosis. Zinc, copper, and all other metals present were determined by chemical or spectrographic method, or both, in liver samples obtained at autopsy from patients with Laennec's cirrhosis and from subjects without evidence of liver disease.

The data obtained indicated that the serum zinc concentration is decreased in Laennec's cirrhosis. In patients with postalcoholic cirrhosis, zinc concentrations in serum and in the liver tissue are markedly lowered. Simultaneously, these patients excrete abnormally large quantities of zinc in their urine; a patient in the terminal state of this disease, however, excreted abnormally low quantities of zinc. The administration of zinc sulfate in physiological quantities tends to restore normal excretory patterns. The Bromsulphalein retention in 5 patients with postalcoholic cirrhosis tended toward normal in the course of these investigations on zinc metabolism. The data are interpreted in the light of the comparative biochemistry of zinc and ethanol metabolism. A conditioned zinc deficiency is conjectured to be consistent with the present data and the known historical, pathophysiological, and pathochemical knowledge of this disease.

Diabetic Coma Without Ketosis. P. Lexow. Acta med. scandinav. 163:115-119 (no. 2) 1959 (In English) [Stockholm].

Occasionally patients with diabetic coma are seen in whom the urine contains no ketone bodies. Reduced kidney function is generally regarded as the cause of this condition, the acidosis being the result of accumulation of ketones in the blood. The author presents the history of 3 patients with diabetic coma and without ketones in the urine; these patients were among about 7,700 persons on whom autopsies were carried out since 1940. All 3 patients were elderly, ranging in age from 61 to 79 years, and 2 of them were known diabetics. There was a gradual development of coma. The blood pressure fell to 90 systolic or below. The blood sugar ranged from 359 mg. per 100 cc. to 1,300 mg. per 100 cc. In 2 cases the urine sugar concentration was approximately 4 times higher than the blood sugar. Reactions for ketones in the urine were entirely negative. All the patients had proteinuria; the level of blood urea was elevated; the alkali reserve was moderately reduced; but none of the patients were anuric. Death occurred from 16 to 10½ hours after the patients became completely comatose.

The author feels that the findings cannot be explained by the old theory of renal retention of ketones. As long as the blood sugar is very high, there is little tendency to ketone formation in the liver. During shock the liver functions are known to be reduced by hypoxia, and the ketogenesis in the liver may be impaired. The acidosis in these cases is considered to be caused by accumulation of lactic acid from anaerobic breakdown of carbohydrates known to take place in shock. The increased resistance to insulin in shock seems to be a result of both stress reaction and depression of the liver functions. The theory is advanced that diabetic coma without ketosis is due to hepatocellular failure during shock. It is impossible to prove morphologically that the lack of ketones is due to hepatic failure during shock. Hepatocellular failure is a functional concept rather than an anatomic one. Accordingly it is of great interest to obtain biochemical determinations of total ketones (including beta-hydroxybutyric acid) and lactic acid in the blood before death in similar cases of diabetic coma.

PUBLIC HEALTH

Comparison of the Number of Breast-Cancer Deaths Observed in Relatives of Breast-Cancer Patients, and the Number Expected on the Basis of Mortality Rates. M. T. Macklin. J. Nat. Cancer Inst. 22:927-951 (May) 1959 [Washington, D. C.].

The author studied sample populations from the State of Ohio to answer the question of whether or not breast cancer in the human being has a genetic basis. The material was collected from June, 1946, through 1952. It was found that grandmothers, mothers, aunts, and sisters of women with breast cancer had breast cancer with a frequency which was significantly greater than that of women in a similar age range, either in the general population or in 2 sets of selected control samples. This excess cannot be entirely environmental in origin, since it was found almost to the same extent in both paternal and maternal grandmothers and aunts. It cannot be attributed to biased selection or to chance distribution of the trait through the population, since the excess was significantly greater than could be accounted for by either of the above factors. Better recall by women with breast cancer, whose relatives were similarly affected, has no bearing on this excess, since the entire family of both control and breast-cancer samples was thoroughly investigated. The ratio of observed-to-expected number of breast cancers is higher in unmarried than in married aunts and sisters. The fact that the presumably genetic factor responsible for this excess of breast cancer is enhanced to the greatest degree in childless women shows the interaction of genetic and extrinsic factors.

Vaccination with V. D. S. Vaccine (Diffusing Vaccine Salvioli) in Dispensaries. S. Taronna. Minerva med. 50:1073-1077 (April 14) 1959 (In Italian) [Turin, Italy].

The author reports on 15,174 children who had been vaccinated in infancy or early childhood against tuberculosis in public dispensaries in Venice, Italy, between 1953 and 1958; the vaccine used was made from killed tubercle bacilli and was known as diffusing vaccine Salvioli (V. D. S.). The children were followed up throughout the school years. Approximately one-half of them (7,492) came from families in which one or more members had tuberculosis during the period of the vaccination program. The tuberculous disease developed in 53 children (0.7%) who were exposed to the active disease at home and in 11 children

(0.14%) for whom there was no evidence of exposure to an active disease at home. The 64 children who were ill had only the first 2 forms of the primary phase of the disease, consisting of simple or allergic varieties of adenopathy or erythema nodosum or allergic pleurisy. A girl, whose father had the tuberculous disease, contracted tuberculous meningitis 2 years after vaccination and died of it. The vaccinal nodule had never developed in this child, and her tuberculin tests had always been negative. This case confirms the assertion of Salvioli that appearance of the vaccinal nodule is a necessary condition for the vaccine to become effective.

These results are compared with the clinical history of 2,908 children who received medical assistance in the same Venetian dispensaries from 1947 to 1953, that is during the years which preceded the vaccination period. Of 2,086 children who were exposed to active tuberculosis at home, 1,122 (53.79%) contracted the disease. Of 822 children who were only slightly, or were not at all, exposed to tuberculosis at home, 385 (46.83%) contracted the disease. In the unvaccinated group the first 2 forms of the primary phase of tuberculosis developed in 1,439 children, a pulmonary or extrapulmonary form of the disease in 55, and a meningeal tuberculous process in 13. No severe general or topical side-effects took place in any of the vaccinated children. Vaccination with V. D. S. vaccine has thus in this series proved to be an effective and harmless means for the prophylaxis of tuberculosis.

General and Socioeconomic Aspects of Pulmonary Tuberculosis as an Epidemiologic Problem. E. Hain. Tuberkulosearzt 13:305-325 (May) 1959 (In German) [Stuttgart, Germany].

Tuberculosis of the lungs is still a major economic and epidemiologic problem despite the considerable reduction in the morbidity and mortality of the disease in the last years. The higher morbidity and the greater incidence of relapses in men are probably attributable to socioeconomic factors (unwillingness to undergo prolonged treatment or to change the type of work because it would involve a loss of income or a descent in the social scale). Although in the population, as a whole, tuberculosis of the lungs takes second place to cardiovascular and unspecific lung diseases as a cause of permanent disablement, it is the commonest cause of invalidism in the younger age groups. This, together with the fact that the disease has a considerably better prognosis than, for example, arthritis or the cardiovascular diseases, renders the rehabilitation of tuberculous patients, particularly those in the younger age group, a matter of the greatest importance.

Tuberculosis has very serious economic effects, not so much because of the expenses involved in the treatment of, and the payment to the tuberculous patient, but because of the considerable loss of man power. For the German Federal Republic the total economic loss caused by the disease has been estimated to amount to 1,000 to 1,500 million German marks, a sum big enough to warrant considerable expenditure for the prevention of the disease and the rehabilitation of the tuberculous patient. Between the fully recovered patients who have returned to their former jobs and the completely disabled persons there is a large group—estimated in the German and English medical literature at from 10 to 35% of all cases of tuberculosis—in which rehabilitation and resettlement are possible. The number of these cases has been estimated at 11,000 for the German Federal Republic.

An Epidemic of Diphtheria in the City and Province of Verona, Italy. P. Montenovesi. Fracastoro 52: 119-130 (March-April) 1959 (In Italian) [Verona, Italy].

The author reports on a clinical and statistical study on the epidemic of diphtheria which struck the city and province of Verona, Italy in October, 1953, and lasted until January, 1955. A total of 671 cases were reported, 463 of the patients being hospitalized. Normally about 100 to 150 cases of diphtheria are reported every year in the same area. Two hundred fifty-nine (55.9%) of the 463 patients who were hospitalized were male, and 204 (44.1%) were female. Of those patients above 2 years of age, 60% were between 2 and 10 years of age, 9.9% were between 10 and 15 years, and 16.1% were over 15 years. The epidemic was more severe during the autumn and winter months. Most of the patients (52.5%) presented pharyngeal diphtheria; 37.8%, rhinitis; 5.6% laryngeal diphtheria; and 1.7%, other forms of diphtheria. Forty-five patients (9.7%) suffered complications involving the kidney; 42 (8.6%), complications involving the nervous system; and 60 (12.9%), complications involving the heart. Eleven (2.3%) patients died; 2 were infants, and 9 were between 2 and 8 years of age; 6 of these patients had suffered a nasopharyngeal localization of the disease. Postmortem examination showed that the immediate cause of death in 8 of the 11 patients who died was a myocardial lesion. Two hundred forty patients (53.5%) had not been vaccinated against diphtheria; the 215 patients who had been vaccinated had received only 2 injections of diphtheric anatoxin, and only 19 of the 215 had received a booster dose. Eight of the 11 deaths occurred among nonvaccinated persons. All the 19 patients who had received a booster dose suffered rhinitis with no complications.

The author believes that from the epidemiologic point of view the episode he studied is to be considered as a periodic recrudescence of diphtheria in a region where diphtheria is endemic. He could not ascertain the cause that provoked the outbreak of this epidemic.

BOOK REVIEWS

The Clinical Evaluation of New Drugs. By fourteen authors. Edited by S. O. Waife, M.D., F.A.C.P., and Alvin P. Shapiro, M.D. Cloth. $7.50. Pp. 223. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1959.

This collaborative work by highly respected authorities in the field presents a survey of the problems and pitfalls involved in the evaluation of a new drug, from its initial study in animals, through clinical trials, until its introduction into general medical practice. The emphasis is on investigation in human patients. The wide range of topics covered includes not only such technical subjects as experimental design and statistical analysis but also the delicate question of the ethics of experimentation on human beings. It is an excellent guidebook "for the many who participate in the search for and evaluation of better and safer drugs to treat human disease." It should prove helpful not only to the investigator but also to the practicing physician whose primary interest is in appraising published reports of drug evaluation and in distinguishing the well-planned and competently executed experiment, on which valid conclusions can be based, from the poor study that permits of no conclusion. The book should be required reading for every student of pharmacology or medicine.

An astonishing number of the reports of clinical trials of drugs published in the current medical literature present nothing more than vague impressions and are better described as testimonials than as scientific papers. Too many give evidence of a lack of appreciation of the rudiments of experimental design, the need for comparison of a new agent with older similar drugs or with placebos, and of the value and limitations of statistical analysis. Frequently, too, there is neglect of the important fact that many diseases are self-limited and that recovery may occur without treatment, the result being that circumstantial improvement is uncritically ascribed to the drug under investigation. Among the many other sources of confusion are the effects of the physician-patient relationship; unconscious bias on the part of the investigator, patient, or ward personnel; and the effects of bed rest, hospital environment, or, in some instances, the physiological effects of sleep. Careful reading of the present volume should enable the untrained investigator to avoid these, as well as less elementary, errors.

The evaluation of new drugs, which are being introduced at an ever-increasing rate, poses a formidable challenge to the physician interested in rational therapy. The difficulty lies in selecting, from the many introduced, those few drugs which are superior to well-established agents or are distinctly different from other drugs in their pharmacological or therapeutic actions. The fact that each new drug, as it appears, seems to gather enthusiastic support for a time, only to be displaced in favor after a brief period by a still newer arrival, hampers dispassionate appraisal. Glowing praise, extravagant claims, and the bombardment by promotional literature to which the physician is subjected further add to the confusion. This book admirably achieves its expressed aim of presenting "a standard against which the practitioner . . . can judge critically the reports of drug research to which he is continually exposed."

Some readers may feel that more detail and fuller treatment of some of the topics would be desirable; however, each chapter is followed by an excellent bibliography. The index is rather sketchy, and consequently information on individual drugs or groups of drugs, scattered through various chapters, may be difficult to find. However, these are minor flaws in a splendid and unique book, one that deserves a place in the library of every physician and medical scientist.

Symposia on Child and Juvenile Delinquency Presented at the American Orthopsychiatric Association. Chaired and edited by Benjamin Karpman, M.D., Chief Psychotherapist, St. Elizabeths Hospital, Washington, D. C. Cloth. $10. Pp. 364, with illustrations by Wesley R. Wilken, Psychodynamics Monograph Series, Station L, Washington, D. C., 1959.

The editor of this volume was chairman of each of the five symposiums whose topics included a general discussion of the psychopathic, delinquent child; his behavior; a differential diagnosis of psychopathy; and the psychodynamics and basic emotional factors of delinquency. This book is a good source of contemporary thinking on the subject. Although the participants presented broadly varied opinions, it was generally accepted that true psychopathy in the child is relatively rare. Most patients presenting antisocial behavior are neurotic delinquents.

A number of etiological factors were suggested. Constitutional inferiority was mentioned by only one contributor but questioned by others. Two patients with psychopathic behavior in whom endocrine dysfunction, namely gonadal imbalance, was present were said to have improved after

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

hormonal treatment. A delay in language development was thought to be a contributing factor in preventing adequate communication with others. The chief etiological factor was considered to lie in inadequate parent-child relationships in the earliest period in life. Children who are raised in institutions without sufficient mothering or those confronted with inconsistent maternal attitudes, may express psychopathic behavior due to a lack of ego development. The critical age for ego development seems to be the first two years of life. Socioeconomic factors or identification with a weak parent or with a delinquent group also may result in psychopathic behavior.

The pathology of psychopathy lies within the ego. A weak ego cannot develop strong affective relationships and results in shallowness of thinking and judgment. Behavioral characteristics of delinquent children include poorly controlled, aggressive, and destructive behavior. Almost all of them show evidence of hostility and project this on others in the environment. Lack of superego control prevents these children from experiencing anxiety as they engage in antisocial behavior. There is no well-defined manner of predicting future delinquency in infants. Children below the age of 7 years may be considered to present predelinquent behavior patterns. The latter can be treated differently from the same patterns in older children.

The development of a close relationship with a therapist may produce changes as the therapist gradually succeeds in setting limits for the patient. Ego development is the essential goal. Constructive changes in the environment are also necessary. Patients one or both of whose parents have also entered psychotherapy seem to have a better prognosis than do the others. It is generally conceded that the older delinquent may not be able to benefit from individual psychotherapy. Placement in an understanding environment that affords consistent limitations seems to offer the best prognosis. While treatment has been touched on in this book, a symposium devoted solely to therapy should prove most fruitful. The various discussions have produced many questions; one of these—why a single member of a family becomes delinquent—remains unanswered.

Shakespeare and Medicine. By R. R. Simpson, M.B., Ch.B., F.R.C.S. Boards. $6. Pp. 267, with illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2; E & S Livingstone, Ltd., 16 & 17 Teviot Pl., Edinburgh 1, Scotland, 1959.

This is a fascinating volume. It appears that of the hundreds of so-called authoritative books on Shakespeare only one has dealt with the medical aspects of his writings. That book was written by Dr. John Bucknill and published in 1860. The numerous papers and essays on the subject that followed were based more or less on the information contained in his scholarly book. Simpson, in the present work, cites some 450 major medical references from the plays and poems of Shakespeare. This number, however, does not exhaust the list for, if minor references are included, the list contains over 700 medical references. To illustrate the medical aspects of the plays of the great bard, Simpson presents an analysis of "Romeo and Juliet" and (in another chapter) a study of Falstaff. A further interesting discussion of some of the medical problems raised in the tragedies is presented in a separate chapter.

Shakespeare's versatility is such that no one book could exhaust even this minor aspect of his creative genius. The present small volume is a worthwhile addition to our understanding of the great English poet. It should prove of great interest to all lovers of literature and particularly to doctors of medicine.

Bleeding Esophageal Varices, Portal Hypertension. By Hirsch Robert Liebowitz, B.S., M.D., Assistant Professor Clinical Medicine, New York University College of Medicine, New York. Section on surgical treatment in collaboration with Louis M. Rousselot, M.D., M.S., Med.Sc.D., Director of Surgery, St. Vincent's Hospital, New York. With foreword by Allen O. Whipple, M.D., F.A.C.S. Cloth. $24.50. Pp. 986, with 179 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1959.

This book had its beginnings in 1950 with a collection of 50 cases of ruptured varices proved at autopsy. The main author began an inquiry into the clinical and pathological features of portal varices and the natural history of patients with bleeding varices. As a result he has reviewed a tremendous amount of literature relating to the circulatory dynamics of the portal system, which review occupies the first third of the book. Extensive references are attached to each chapter. Many of the factors concerned with the pathogenesis of portal hypertension and esophageal varices are incorporated in later chapters dealing with clinical problems. Some of these chapters are followed by summaries while others are not. Dispersed throughout the book are case reports contributed by and based on the experience of both authors and critical reviews of other cases reported in the literature.

Dr. Liebowitz concludes that increased hydrostatic pressure is the fundamental mechanism of varix rupture, regardless of the state of the overlying mucosa. Discussions follow concerning hepatic portal cerebral encephalopathy, ascites, the diagnosis of esophageal varices, splenic portography, and medical management of bleeding varices. The combined pressure and signal apparatus designed by Kulick and Rousselot is analyzed. The concluding section of the book concerns itself with the discussion of surgical management of portal hypertension and the use of portacaval shunt. However, no definite stand is taken on the controversial topic of the emergency portacaval shunt. Although this volume represents a monumental contribution in terms of a review of the pertinent literature, the book suffers from a lack of conciseness. As noted in the foreword "this large monograph deserves careful reading, and will be most rewarding to anyone who has had to deal with the problems associated with portal bed block and portal hypertension." Unfortunately, the size of the monograph may deter some prospective readers.

The Degenerative Back and Its Differential Diagnosis. By P. R. M. J. Hanraets, M.D. Translation by Miss M. E. Hollander. [*Thesis, M.D., Roman Catholic University at Nijmegen.* Title: The Weak Back: A Medical Study of the Endogenous Components of Disorders of the Back, Which is Then Called: A Degenerative Back.] Cloth. $19.95. Pp. 690, with 315 illustrations, photographs by W. Maschhaupt, drawings by P. v. d. Maaden. Elsevier Press, Inc., Bank of Southwest Building, Houston 2, Texas; Elsevier Publishing Company, 110 Spuistraat Amsterdam C, Netherlands; D. Van Nostrand Company, Ltd., 358 Kensington High St., London, W. 14, England; D. Van Nostrand Company (Canada), Ltd., 25 Hollinger Rd., Toronto 16, Canada, 1959.

This extensive volume is interesting but difficult to read, because the style is often confusing. This is mentioned to emphasize the fact that this is not a book to be hastily read but rather to be carefully and slowly digested, chapter by chapter. The whole volume deals with degenerative lesions in the back; early in the book, the author states that, although most of the backs he sees have degenerative lesions, the patients should not be told this. The reason for this approach is not clear.

The first few chapters are general in nature and deal with the causes of the multiple degenerative changes that may appear in the spine, including those of the bony structures, changes in the mineral content of bone, facet changes, changes within the disk, and changes in the associated muscles, blood vessels, and nerves. Several excellent colored photographs show many of the anomalies in the nerve roots which, the author feels, definitely contribute to the degenerative lesions. He also states that degenerative back lesions may be a manifestation of a certain type of personality structure and that psychic disturbances can precipitate or aggravate this condition.

As to treatment, the author favors two operations. The first is complete laminectomy combined with extensive foraminotomy. The explanation given is that the laminas do not enter into the stability of the spine and therefore can be sacrificed and that the chief area where the nerve root is likely to be constricted is at the foramen. These two points are debatable. The second operation is the selective extradural rhizotomy of the nerve root for the relief of pain. He admits that this is a difficult procedure. The third and probably the most radical idea presented is the "overhaul operation" in which many levels are explored at one time. This book is very interesting but likely to provoke much discussion. It is difficult to accept all of the author's views. It should prove interesting chiefly for those who frequently must treat the degenerative back but is far too complex to be given to students as assigned reading.

Transplantation of Tissues: Skin, Cornea, Fat, Nerves, Teeth, Blood Vessels, Endocrine Glands, Organs, Peritoneum, Cancer Cells. Volume II. Edited by Lyndon A. Peer, M.D., Clinical and Research Director, Rehabilitation Center for Plastic and Reconstructive Surgery, Saint Barnabas Medical Center, Newark, N. J. With twelve contributors. Cloth. $20. Pp. 690, with 252 illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2, 1959.

This volume is the joint effort of 13 contributors, each discussing a different variety of tissue transplant. They describe how tissue, organ, or gland transplants may be grafted and discuss the limitation, success, or failure of the procedure. Organs including skin and cornea, endocrine glands, teeth, blood vessels, fat, and nerves are among the many transplants discussed. The bibliography and index are of special value. This book is enthusiastically recommended to everyone in the field of medicine.

Practical Obstetric Problems. By Ian Donald, *M.B.E.*, M.D., B.S., B.A., Regius Professor of Midwifery, University of Glasgow, Glasgow. Second edition. Cloth. $11. Pp. 712, with illustrations. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11; Lloyd-Luke (Medical Books) Ltd., 49 Newman St., London, W. 1, England, 1959.

This new edition of a four-year-old textbook includes the new and important developments of the intervening years. The book is written primarily for the clinician as a convenient source of information concerning practical problems in obstetrics. To achieve this end the chapters on anatomy, embryology, and physiology of reproduction usually found in current textbooks have been omitted. The book begins with a discussion of prenatal care and ends with chapters on prematurity and the Rh factor. The management of all the pertinent problems encountered in pregnancy, labor, and the puerperium is discussed in a lucid and authoritative manner. Characteristically, one chapter is entitled Techniques and Pitfalls of Forceps Delivery and another Postpartum Collapse.

Although most of the chapters were written by the author, several were contributed by well-known British authorities. One of these contributions in particular reflects its author's profound clinical experience in his evaluation of trends in obstetric practice, such as the increased frequency of the induction of labor, induction for postmaturity, and the importance of the prevention of puerperal infection.

In general, obstetric practice in England is similar to that in the United States. Although there has been an increase in hospital births, many women are still delivered in their homes. To provide for emergency services, the "flying squad" brings most of the hospital medical facilities to them there. Some of the practices described are not used in the United States. For example, we would not include a discussion of symphysiotomy in an American textbook. Pertinent and recent references are given at the end of each chapter. The illustrations are few in number but informative and complementary to the text. This book can be read with profit by physicians and students interested in obstetrics.

Allergie und allergische Erkrankungen. Band I, allgemeiner Teil. Unter Mitarbeit von R. Backhausz et al. Herausgegeben von E. Rajka. Cloth. Pp. 638, with 74 illustrations. Akadémiai Kiadó, Alkotmány u. 21, Budapest, V, Hungary, 1959.

This volume, written with the collaboration of eight Hungarian contributors, deals with general and basic considerations. The author takes the attitude that the tie between allergy and immunology is progressively becoming closer, so that one cannot be discussed without the other. Among the subjects covered are criteria; classification and terminology; distinction between immediate and delayed types; antigens and antibodies and factors in the antigen-antibody reaction; antibody production, mediators (including histamine, acetylcholine, serotonin, and slow-reacting substance); the immunochemistry of antigens and antibody; experimental anaphylaxis; autosensitization; transplantation and tumor immunology; the role of the neuroendocrine system; pathological anatomy; the production of allergic processes; general diagnostic measures in allergy; various serologic tests in allergy and immunology; and general principles of management of allergic manifestations. In virtually all of the above subjects the most important phases are discussed, so that the reader can find at least a summary of any field bearing on hypersensitivity.

References are ample although no attempt is made to include the very old literature, as this has been covered by older textbooks. There is a tendency to overemphasize the European contributions and to underplay the American ones. The paper is excellent, but the binding is poor. As a whole, this is the most complete treatise available on the principles of allergy and a book to be owned by those allergists, immunologists, internists, pediatricians, and all others interested in immunological principles who have a reading acquaintance with German.

Parsons' Diseases of the Eye. By Sir Stewart Duke-Elder, G.C.V.O., Ph.D., D.Sc., Surgeon-Oculist to the Queen, London. Thirteenth edition. Cloth. $8.75. Pp. 613, with illustrations. The Macmillan Company, 60 Fifth Avenue, New York 11; J. & A. Churchill, Ltd., 104 Gloucester St., Portman Sq., London, W. 1, England, 1959.

Many a student's introduction to ophthalmology was through an earlier edition of this fine textbook, and for this reason it is a particular pleasure to reread it and rediscover its fine qualities. The entire field of ophthalmology is covered briefly and concisely but with sufficient detail to leave few questions unanswered, and the book has been brought up to date. Some new chapter headings have been added and some change in the order has been made. The two final chapters entitled The Causes and Prevention of Blindness and The Hygiene of Vision, which were also included in earlier editions, are particularly worthwhile, since most textbooks ordinarily do not discuss these subjects from the preventive viewpoint. This book is heartily recommended for all physicians, but particularly for general practitioners. Residents should also find it of great benefit and practicing ophthalmologists should enjoy reading it.

Progress in Hematology. Volume II. Edited by Leandro M. Tocantins, M.D. With 19 contributors. Cloth. $9.75. Pp. 290, with illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 15/16 Queen St., Mayfair, London, W. 1, England, 1959.

This series of 13 reviews of aspects of hematology is especially valuable for its extensive bibliography. Each contributor uses this material to uphold his side in controversial matters. The illustrations in the article entitled Contributions of Dynamic Cytology to Hematology are graphic and illuminating. Among the subjects covered are cytology, radiation injury and bone marrow transplantation, the sickling phenomenon, humoral factors in erythropoiesis, kernicterus, ABO incompatibility and hemolytic anemia in the newborn infant, blood preservation for transfusion, transmission of leukemia, hematological aspects of serotonin, busulfan in the treatment of leukemia, platelet transfusions, hematological complications of esophageal varices, and lipoid anticoagulants. The index is very useful. The book should be valuable to anyone studying the subjects covered, for the analyses of the material as well as for the bibliography.

Textbook of Oral Surgery. Edited by Gustav O. Kruger, B.S., A.M., D.D.S., Professor of Oral Surgery, Georgetown University School of Dentistry, Washington, D. C. Cloth. $12.75. Pp. 573, with 489 illustrations, including drawings by Biagio J. Melloni. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3; Henry Kimpton, 134 Great Portland St., London, W. 1, England, 1959.

This textbook, written entirely by dental personnel, is intended as a reference work for the undergraduate dental student. The first five chapters deal with surgical principles, techniques, bacteriology, infections, hemorrhage, and shock. They emphasize fundamental surgical teachings and are sound. Additional chapters describing abnormalities and diseases of the oral cavity are informative and worthwhile. However, the complicated surgical problems mentioned in the chapters on wounds and injuries of the soft tissues of the face, the surgical aspects of the cleft lip and cleft palate, and complicated malignant oral tumors are beyond the scope of the dental student and dental surgeon.

QUESTIONS AND ANSWERS

STATUS OF SNAKE BITE THERAPY

To the Editor:—*There has been so much controversy regarding treatment of bites from venomous snakes that I would appreciate a reasonable evaluation of this matter. The relative incidence of snake bite in the United States is quite low and therefore most physicians will rarely encounter such a case; however, I am sure such a general evaluation would be useful to everyone.*

M.D., Illinois.

Answer.—Controversies regarding the proper treatment of envenomation due to pit vipers are focused especially on use of tourniquets, cuts, and suction and on the ligature-cryotherapy method of Stahnke (1957). Currently, the brochure accompanying the antivenin distributed by Wyeth states that neither procedure should be used.

Evidence both for and against these procedures rests on only rather limited to-the-point studies. The work of Dudley Jackson (1927, 1929) and of Pope and Peterson (1946) indicated that envenomated dogs treated by tourniquets, cuts, and suction did better than control dogs. The published studies of Parrish (1955), of Leopold and his group (1957), and Ruggiero (1958) do not directly contradict the findings of the earlier workers. Parrish; Andrews and Pollard (1953); Watt (1956); Jutzy and his group (1953); Shannon (1957); Raynolds (1959), Schmaus (to be published); and Stahnke have recommended tourniquets, cuts, and suction, some with stipulations.

Shortcomings can be noted in Jackson's work, and clinical observations without controls may be misleading. Nevertheless, at least until studies now in process are published, the balance of evidence seems to indicate that the tourniquet, cut, and suction treatment has value. Jackson and Shannon have advised the making of cuts along the advancing edema front, if necessary far from the injection site. A snake usually injects less than 10 drops of venom. In the absence of evaluating studies, this consultant believes that cuts should be few and near the injection site.

No controlled studies of the ligature-cryotherapy method have been published, and Stahnke has reported only a small series of clinical cases. Controlled studies are needed to appraise the procedure as a first-aid method until antivenin is given and as extended medical treatment.

Concerning other aspects of therapy, the stricken person should remain immobile until antivenin is given. The Wyeth antivenin appears to be definitely helpful against pit vipers. It should be given early and in adequate amounts. Antibiotic therapy is needed. Parrish and co-workers (1956) have advised that a broad-spectrum antibiotic be used. Penicillin, however, is more effective against clostridia. Some evidence indicates that gas gangrene and tetanus are dangers; therefore, appropriate prophylaxis is advisable. The heart of treatment against shock appears to lie in blood transfusions. The use and choice of pressor substances must reflect general medical theory, for there are no controlled studies with them in snake bite cases. Corticosteroids apparently do not prolong or save life, according to experimental work, but Wood's (1955) patients seemed to derive much symptomatic benefit from them. Schöttler (1954) advised against antihistaminics on the basis of studies with mice, but the drugs have been given without apparent ill-effect in some human cases. Cold packs may give considerable symptomatic relief locally.

FOOD INTAKE BY LOGGERS

To the Editor:—*The modern logger, like the coal miner, is mechanized. A smaller work force handles much more wood by using chain saws and mechanical loaders. Previously, the loggers consumed fabulous quantities of food. Now camp cooks have noted a decrease in the amount of food used, especially in carbohydrate items, and an increase in the amount of meat consumed. Since the men have a wide choice of food at each meal, this change is voluntary. Do you know of any study of loggers' changing food requirements as a result of mechanization? Also, do you believe that the decreased carbohydrate intake and increased meat consumption are related to the decrease in physical effort?*

Leslie G. Sutherland, M.D.
Peterborough, Ontario, Canada.

Answer.—This consultant is not aware of any studies of the food consumption of loggers since those made in camps located in the Pacific Northwest and Great Lakes regions by Alpert, Lusby, and Goodhart in the spring of 1943 (cited in "Nutrition in Industry," Montreal, International Labour Office, 1946, pp. 89-92). These workers found the average daily calorie consumption in four different camps to range from 5,311 to 6,507, it being high-

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

est in camps located in the Pacific Northwest. The food and nutrition board of the National Research Council, on Jan. 29, 1944, adopted a report of its committee on nutrition of industrial workers which, for rationing purposes, recommended that loggers, and loggers alone, be placed in a category of workers requiring more than 5,500 calories per day.

In regard to the consumption of meat by loggers, Alpert, Lusby, and Goodhart made the following pertinent observations: "Traditionally, logging companies have tried to provide the loggers with an abundance of good quality food because this contributes to satisfaction with the work and a decrease in labour turnover. The loggers have a firm conviction that large amounts of meat are necessary in order to log. They believe that they cannot keep up the pace necessary, or do the heavy work required without meat at each meal. Meat alternate dishes such as macaroni and cheese, baked beans, creamed codfish, and scrambled eggs are considered 'side-dishes' and to be served as additions to the meat, not in place of it."

The decreased food intake noted in this question after decreased physical effort is in accordance with the hemostasis of energy metabolism. As their work output increases, normal healthy persons will automatically consume a larger number of calories, if available, to maintain an energy balance, and vice versa. Since the requirement for protein is relatively uninfluenced by the amount of physical work, it would be entirely physiological for loggers with a free choice of food to cut down automatically on the consumption of high-calorie carbohydrate and fat foods such as cakes and pastries.

ANXIETY NEUROSES

To the Editor:—*In the management of anxiety neuroses after ruling out organic disease, how does one explain to the patient the reason for his symptoms? Please suggest methods of coping with hyperventilation syndrome, aerophagia, globus hystericus, and fatigue and insomnia. What is the value of tranquilizers or sedatives in these conditions? How are they best prescribed?*

M.D., New York.

Answer.—The explanations for psychosomatic symptoms have to be geared to the patient's intelligence and education. In many cases, the physician should not tell the true reason for the anxiety neurosis even to highly intelligent patients because the explanation might be of such a shocking nature that the patient might refuse the explanation and leave the physician's care. It might also make psychotherapy difficult for another physician. Such is the case, for instance, if the anxiety is caused by latent homosexuality. The best way to inform the patient is not to emphasize the psychogenic origin of his or her symptoms but to give an explanation in understandable neurophysical terms. Such an explanation should emphasize that overexcitability of the sympathetic nervous system would produce, *ipso facto*, anxiety symptoms. The possible psychological reason for this assumed excitability might be hinted at but not necessarily explained in detail to the patient.

If the physician and patient are unwilling to embark on long-term psychotherapy for the treatment of hyperventilation syndrome, aerophagia, globus hystericus, and fatigue and insomnia, carbon dioxide treatment would be useful. Use of tranquilizers and sedatives should be avoided in a patient with these symptoms, because of the danger of developing addiction. Besides, most of the tranquilizers which are effective against anxiety will increase the patient's complaints of fatigue. If absolutely necessary in such a case, a medicament consisting of a combination of tranquilizer and stimulant might be tried, *cum grano salis*. There are several of these on the market, each of which contains either a barbiturate or chlorpromazine with amphetamine. In extreme cases of anxiety, with the combination of symptoms described above, electric shock treatment might be of service.

STEROID THERAPY IN COLON POLYPOSIS

To the Editor:—*A man 40 years of age developed chronic ulcerative colitis five years ago. The disease has followed a mild course, with only a few exacerbations. Recently, a routine sigmoidoscopy revealed true polyps in the sigmoid. On removal, these showed no evidence of malignancy in histological section. Barium enema showed some remaining polyps above the reach of the sigmoidoscope. If the colon were opened and the remaining polyps removed, would prolonged steroid therapy lessen the chance of further polyposis occurring?* *M.D., Pennsylvania.*

Answer.—"True" polyps probably indicate "adenomatous" polyps. The prevailing opinion, based largely on circumstantial evidence, is that they may undergo malignant transformation. Therefore, removal seems advisable. In the case described, however, the polyps above the reach of the proctoscope may be true polyps or pseudopolyps. The differentiation on radiologic and clinical grounds is difficult. The decision whether to remove them or a portion or all of the colon is difficult, depends on other considerations, and is controversial. One should bear in mind the fact that a third of carcinomas of the colon in ulcerative colitis arise as infiltrating lesions without an intermediary phase of polyposis. In some instances when careful follow-up studies at fixed intervals in patients with ulcerative colitis are possible, roentgenologically demonstrated polyps or pseudopolyps may be watched rather than proceeding with colectomy. No studies have been made as yet of the occurrence of polyps or pseudopolyps before and after prolonged steroid therapy. Of the patients with ulcerative colitis who have died from carcinoma of the colon, an insignificant number have had steroid therapy. There is as yet no evidence available to indicate whether ACTH and the adrenal steroids enhance or lessen the risk of malignancy in the colon. The role of these hormones in the therapy of ulcerative colitis is still debatable, even though this consultant is strongly of the opinion that they are quite helpful.

POLYARTERITIS AND ALLERGIC ANGIITIS

To the Editor:—*At a recent medical meeting it was obvious that there was no agreement on the differentiation between polyarteritis nodosa and allergic angiitis. Please comment and/or give bibliography.*

M.D., West Virginia.

Answer.—It is understandable that confusion should exist concerning the differential diagnosis of these two conditions, for they are closely related if not identical diseases. Clinically, both conditions are characterized by fever, malaise, and protean symptoms due to involvement of multisystems. Typically, the onset of allergic angiitis can be precisely related to administration of a drug or exposure to certain chemicals, and there is usually a history of hypersensitivity to other agents as well. Eosinophilia, bronchial asthma, and cutaneous manifestations such as purpura and subcutaneous nodules are seen more commonly in allergic angiitis than in periarteritis nodosa, in which the history of exposure to an allergen is less definite or entirely lacking. Some pathologists claim these conditions can be distinguished histologically as well as clinically, even though the basic lesion in both is an acute arteritis involving small arteries with necrosis and polymorphonuclear infiltration of the vessel wall.

From the practical standpoint, most cases are not easily categorized, since one or more of the differentiating features may be lacking. The differential diagnosis is usually of only academic interest, because treatment (adrenal steroids) is the same for the two conditions and prognosis, though said to be somewhat better for allergic angiitis, is not too dissimilar in most cases of systemic involvement. The references given below are pertinent.

SAFETY OF X-RAY APPARATUS

To the Editor:—*In my office I have a small diagnostic x-ray machine which is usually operated at 15 ma. and 90 to 120 volts. The estimated primary radiation is about 540 ma.-sec. per week. There is no fluoroscope attachment. Please describe practical methods for measuring the amount of radiation being sustained by my employees and myself. I have been told that a person may be exposed to 0.3 rem per week for an indefinite period without danger; what is a rem and how can this be measured? What is the level of radiation exposure beneath which it is safe to have no lead shielding, assuming an indefinite exposure period?*

Robert C. Foreman, M.D., Goodyear, Ariz.

Answer.—It would be advisable for this inquirer to have a radiation physicist measure his x-ray apparatus and determine its safety. Lead shielding is a necessity for all operators. There is no safe exposure for persistent exposure to irradiation even from a supposed small dose. At present the permissible whole-body exposure to gamma rays and x-rays is set at 0.3 r per week. There are a number of companies that supply special monitoring badges which measure the exposure a person receives while administering x-rays. These concerns advertise in The Journal and in the journals of the national radiologic societies. National Bureau of Standards Handbook 59, available from the U. S. Bureau of Standards, Washington, D. C., describes regulations concerning x-ray exposure limits. The rem is a dosage unit. It is the quantity of any ionizing radiation which has the same biological effectiveness as 1 rad of x-ray in the usual energy range. (The rad is a base unit for beta rays and is 100 ergs absorbed per gram of material in question.)

ARC LIGHTS AND STERILITY

To the Editor:—*A patient whose husband works with electric arc lights (the type used in the war in searchlight units) has just delivered a stillborn infant. Their friends, who are also exposed to these lights, have had stillborn children or no children. Is there a relationship between male exposure to arc lights and sterility or stillborn infants in their family? If so, what advice should be given to such persons in regard to future childbearing?*

M. R. Hunter, M.D., Olympia, Wash.

Answer.—Though the reproductive mechanism of some fish and some fowl seems to be light-sensitive, no analogous data are to be found for man. During World War II, the Westinghouse Electric Co. made the xenon mercury light which was similar to the arc light referred to in the question. The rays produced depend, among other things, on the type of generator and the amount of voltage employed. A system of lenses acts as a filter. As a general rule, the rays produced were of a wave length of about 1,800 A. With wave lengths over 2,000 A, some ultraviolet light is generated. If not filtered out, this will simply produce pigmentation of the skin. Even with the low voltages employed, a small amount of x-radiation is generated. This is filtered out by the lens system. However, if voltages of the order of 70 kv. or higher are employed, as much as 30% of the rays produced may be x-rays. If not effectively filtered out, this radiation may render the male sterile. No effect has been described, however, which will cause stillbirth. Where high voltages are used and filtration cannot be assured, avoidance of the x-rays or the use of lead shields is desirable. If that cannot be managed, a change of employment should be considered.

FROZEN BABY FOODS

To the Editor:—*Have frozen fresh strained and chopped vegetables, fruits, and meats been placed on the market specifically for infant feeding? Have the present canned baby foods been accepted as the final word in infant feeding? I have used frozen fresh strained foods for my own children with excellent results. I feel others would be equally pleased.*

L. B. Stevens, M.D., Baltimore.

Answer.—This consultant is not aware of any manufacturer producing frozen baby foods. At the recent National Packaging Exposition, it was reported that frozen precooked baby foods in aluminum pouches may be available in supermarkets by the end of the year. According to Reynolds Metals, several manufacturers are considering the food pouch.

It is not known why such products have not appeared on the market before, but the cost factor probably is greater in the freezing process. Perhaps inquiry of some of the larger baby food manufacturers, such as Gerber, Heinz, and Beechnut, would provide more information on this subject.

SURGICAL GLOVE DERMATITIS

To the Editor:—*Because of contact dermatitis due to rubber gloves, I changed to latex rubber gloves several years ago and the dermatitis largely cleared. Recently I have become allergic to the latex gloves. Have any other types of surgical gloves been developed out of plastic?*

James L. Petry, M.D., Port Arthur, Texas.

Answer.—The information in this letter is incomplete. It is difficult to understand whether, when the inquirer changed from ordinary gloves to those made of latex, his dermatitis was relieved entirely. If it was not entirely well, then it would be impossible to state whether the patient became allergic to the latex gloves or whether use of these or any other type of rubber gloves might be responsible for continuation of the dermatitis. To determine whether this is mechanical irritation or a true allergy, it would be desirable to patch test with the rubber, the latex, and with specific ingredients of each, if these can be obtained. There have been no new plastics developed which are satisfactory substitutes for rubber. This physician might be interested in reading an article in *Occupational Hazards* (21:43, 1959) entitled "Are Your Gloves Right for the Job They're Doing?"

Inquiry was made to Donald J. Birmingham, dermatologist for the U. S. Public Health Service. He suggested the use of a glove made of a brown milled heavier rubber.

MOTTLING OF PALATE

To the Editor:—*A middle-aged female was referred to me by her dentist because of a whitish mottling of her palate extending from the gingival margins of the upper teeth for a half an inch or so out onto the palate. It has been asymptomatic. Because of some plaque formation, the dentist was concerned about the possibility of malignancy. Since the process is rather widespread, with no one area showing unusual thickening, I have not done a biopsy. I have treated the area with silver nitrate on several occasions, with no appreciable change, although it did seem gradually to regress until lately. Please give an opinion as to probable diagnosis.*

Lewis I. Younger, M.D., Winona, Minn.

Answer.—The information given does not permit a clear conception of the condition present but suggests it most likely would be focal hyperkeratosis or leukoplakia. However, the possibility of lichen planus cannot be eliminated. It is suggested that a biopsy be made to establish diagnosis.

ELECTROCONVULSIVE THERAPY AND EPILEPSY

To the Editor:—*About 1 to 2% of patients have a grand mal seizure after electroconvulsive treatment given with thiopental and succinylcholine by an anesthetist. A follow-up electroencephalogram is always normal. What could be the cause of the seizure? The patients also receive physiological oxygenation before and after treatment.*

M.D., New York.

Answer.—Electroconvulsive therapy in some instances has a tendency to potentiate already abnormal electrical patterns in the brain. One might assume that in some other instances there is a build-up of uninhibited electrical potentials in the cortex after electroshock. The mechanism is not exactly known, however. It is known that patients may develop epilepsy after electric shock from lightning. Electroencephalograms should be done frequently and for a long period of time, since there have been experiences of epilepsy after electroconvulsive therapy.

DOG AS PINWORM CARRIER

To THE EDITOR:—*I will appreciate your opinion on the possibility of dogs being carriers of pinworm (Enterobius vermicularis) and causing human infections. So far as I can learn, the dog is not a natural host or carrier of this species.*

M.D., New York.

ANSWER.—Humans are the sole natural host of E. vermicularis, perhaps the commonest of man's parasites. Transmission of infective ova can occur by any of the innumerable channels through which the fecal excretions of one man are carried to the mouth of another. It is probable that direct personal contact between persons provides the most common mode of transmission. House pets, including the dog, have been shown to play no role in spread of this infection. Enterobiasis has been reported for other animal species. Horses, for example, may be infected with E. equi and some rodents with Syphacia obelata. Human infections have been reported with the latter parasite, but not by passage through dogs.

MALIGNANT ERYTHROCYTOSIS

To THE EDITOR:—*Please indicate the treatment of malignant erythrocytosis (Di Guglielmo's disease) in a 4-year-old child.*

Edwin M. Meek, M.D., Greenwood, Miss.

ANSWER.—Malignant erythrocytosis is a condition for which there is no known treatment except symptomatic care. When patients suffering from this condition are anoxic, transfusions are indicated. None of the agents used in leukemia has been found to be effective in this condition. Apparently the immature and anarchistic red blood cells do not respond to suppression as white blood cells of a similar nature do. Therefore, there is no real help that can be given to any patient with this syndrome.

CHICKENPOX IN EARLY PREGNANCY

To THE EDITOR:—*I would like to know if there is any danger to the child if and when the mother contracts chickenpox during the early first trimester of pregnancy. Is gamma globulin indicated if the infection is extremely mild?*

M.D., Illinois.

ANSWER.—There is practically no danger to the child when the mother contracts chickenpox. Gamma globulin is not indicated.

GELATIN AS FUNGICIDE AID

To THE EDITOR:—*For 10 years a patient had microscopically demonstrated ringworm infection of the fingernails which resisted all usual methods of treatment until gelatin, in the form of dessert, was added to the daily food intake. Then Whitfield's ointment, double the U. S. P. strength, effected a complete cure when applied daily, despite previous failures. Please advise as to any reports on use of gelatin as an adjunct with a fungicide in this frequently intractable disease.*

M.D., Florida.

ANSWER.—No report in the literature is known on oral administration of gelatin to supplement treatment of ringworm of the nails. The observation reported is interesting. It should be supported by study of a large series of cases in order to afford more valid conclusions.

COUGHING AFTER CATARACT OPERATION

To THE EDITOR:—*The response to a question on coughing after cataract extraction* (J. A. M. A. 169:*1546 [March 28]* 1959) *contained information which might be misleading. The answer stated that long-acting inhibitors of cholinesterase, such as acetazolamide, chlorothiazide, and ethoxzolamide, could be used to maintain (i. e., lower) the intraocular pressure. Acetazolamide and ethoxzolamide are inhibitors of carbonic anhydrase, not of cholinesterase, and of course are valuable agents for lowering intraocular pressure. Chlorothiazide has shown significant carbonic anhydrase activity in vitro and may have some of this activity in vivo, although its mechanism of action is not precisely known. However, chlorothiazide is not generally effective in lowering intraocular pressure.*

Charles Aronberg, M.D.
401 S. Cochran Ave.
Los Angeles 36.

The above comment was referred to the consultant who answered the original question, and his reply follows.—ED.

To THE EDITOR:—*The physician who took exception to the use of the term cholinesterase is correct. Through a typographical error, cholinesterase was used rather than the correct term carbonic anhydrase. The drugs mentioned are effective inhibitors of carbonic anhydrase. There is no qualified evidence that chlorothiazide acts to lower intraocular pressure; therefore, it cannot be considered a useful drug in the treatment of glaucoma.*

Poliomyelitis Rate . .

BROADER MEDICAL EXCHANGES WITH SOVIET UNION PROPOSED

Russian and American officials discussed increased medical research cooperation between the two nations during Russian Premier Nikita Khrushchev's visit to this country.

The informal talks were held during a morning tour of the National Institutes of Health by Khrushchev's personal physician, Dr. A. M. Markov and his companion and interpreter, Dr. V. N. Butrov. They were guided around NIH's 14-story clinical center by Arthur S. Flemming, Secretary of Health, Education, and Welfare; Dr. Leroy E. Burney, U. S. surgeon general; and Dr. James A. Shannon, assistant surgeon general and director of NIH.

Khrushchev himself had been slated to see the NIH in Bethesda, Md., but canceled the trip due to the press of other business. Dr. Markov is chief of medical service for the Kremlin and a member of the Collegium of the Ministry of Health.

Welcoming the visitors, Dr. Burney declared, "No nation, seeking better health, takes it from another; and the gains of any nation help everywhere to advance this common cause of mankind."

Replying, Dr. Markov said, "The doctors of our two countries can certainly get together, and help the health of people throughout the world."

Types of exchanges and research projects that would be most fruitful were discussed during the visit. Particular interest was shown in research on poliomyelitis, cancer, and heart disease. However, asked which "disease" he would like to see most progress on, the gray-haired Russian physician said with a smile, "Old age."

There was talk of expanding the present medical exchange program to send eight teams of American scientists to Russia and an equal number of Russian groups to this country before the end of the year. A participant in the discussions said joint research projects might include either splitting up the work or working in the same field and comparing results.

Formal exchange agreements were to be worked out after Khrushchev returned to Russia.

Meanwhile, Sen. Hubert H. Humphrey (D., Minn.), Chairman of the Senate government operations subcommittee on international health, said that "inadequate financing" of U. S. physicians' travel to the Soviet Union "remains a key handicap." He said he "will be working on this problem in next year's appropriations legislation."

According to a progress report compiled by the subcommittee on the exchange programs between the U. S. and Russia in all fields, including medical, the HEW Department stated that "the problem of financing East-West exchanges has become a major deterrent in planning future exchanges in its field . . ."

In another development involving international cooperation, HEW Secretary Flemming revealed that the U. S. government is making special voluntary contributions totaling 6 million dollars to the World Health Organization and the Pan American Health Organization. All told, the official said, the United States will spend some 100 million dollars on international health activities during the current fiscal year. This would be about 20 million dollars more than last year. "This kind of investment helps people all over the world," Flemming told a news conference. "Rapid progress is emerging in this field."

Flemming also said that increased cooperation with Russia probably will involve, among other things, exchanges of research scientists to work in laboratories of both countries to familiarize themselves with different methods of research.

DRUG PRICE INQUIRY SCHEDULED

The Senate antitrust subcommittee, headed by Sen. Estes Kefauver (D., Tenn.), scheduled hearings starting Nov. 30 on retail prices of drugs. Prices charged for drugs used in treating arthritis will be the lead-off subject. Later the subcommittee plans to investigate prices of antibiotics, antidiabetic drugs, hormones, and tranquilizers.

In announcing the sessions Senator Kefauver said he had received more complaints from the public about the prices of drugs in the last two years than about those of any other group of products. "Prominent among these complaints are letters from older people about the prices they must pay for drugs used in the treatment of arthritis," he said in a statement.

"There are more than 10 million people in the United States suffering from rheumatic diseases, 1 million of them permanently disabled. Many of the older people say their income consists of their social security benefits and that, after paying for the drugs, they do not have enough to live on," he said.

At previous congressional hearings on drug prices, the drug industry has pointed out the high cost of the extensive research programs that drug companies continually carry on to improve their products and develop new ones.

The Senate investigation had originally been slated to begin during the previous session of Congress but was postponed.

The subcommittee disclosed it had subpoenaed the records of some major New York City banks, investment companies, and mutual funds and those of 20 drug manufacturers.

The hearings are part of a series of sessions on so-called administered price industries. Senator Kefauver contends that in some industries prices are set more by agreements among manufacturers than in response to supply and demand. However, industry representatives have denied this at the Senate hearings.

The drug companies whose records were subpoenaed were American Cyanamid Co.; American Home Products Corp.; Bristol-Myers Co.; Olin Mathieson Chemical Corp.; Chas. Pfizer & Co., Inc.; Sterling Drug, Inc.; Carter Products, Inc.; U. S. Vitamin & Pharmaceutical Corp.; and Vick Chemical Co.; all of New York; Eli Lilly & Company, Indianapolis; Parke Davis & Company, Detroit; Abbott Laboratories, North Chicago, Ill.; Merck & Co., Inc., Rahway, N. J.; Schering Corporation, Bloomfield, N. J.; Smith Kline & French Laboratories, Philadelphia; G. D. Searle & Co., Skokie, Ill.; The Upjohn Company, Kalamazoo, Mich.; Warner-Lambert Pharmaceutical Co., Morris Plains, N. J.; Mead Johnson & Company, Evansville, Ind.; and Norwich Pharmacal Co., Norwich, N. Y.

AGE LIMITS PROPOSED FOR AIRLINES PILOTS

The Federal Aviation Agency recommended that all airline pilots be retired at the age of 60 years and that jet aircraft pilots be no older than 55 years.

The Airline Pilots Association objected to the proposals and urged the FAA to hold hearings on the matter. The association contended that pilots should be allowed to fly as long as they are found physically and mentally capable, regardless of their age.

Generally agreeing with the agency was the Air Transport Association, representing the airline industry, which declared that current medical knowledge showed a definite susceptibility for medical deficiencies to increase with age. However, the ATA said it recognized that any maximum age limit is arbitrary and that there would be "good pilots in any given age group who would be in sufficiently good condition that they could continue flying beyond the age limitation."

The ATA disagreed with the 55-year age limit for jet pilots, saying that this would cause "unnatural and undesirable stresses" on the airlines and their personnel.

The Civil Aviation Medical Association and the Civil Air Surgeon's office both supported the recommended age limits. The FAA recently set strict health standards for both commercial and private pilots, disqualifying those with certain types of diabetes and heart disease, among other conditions.

REPORT ON POLIOMYELITIS RATE

After declining for two weeks, the incidence of paralytic poliomyelitis increased abruptly to 326 cases during the week ended Sept. 19, the second highest number reported for any week this year. In contrast, 273 paralytic cases were listed for the week ending Sept. 12 and 291 for the previous week. Highest total for the year was 330 for the last week in August.

PHS said preliminary estimates indicate 150 deaths from poliomyelitis as of July 31 this year, compared with 10 at the same time a year ago. However, the poliomyelitis season started much earlier this year.

Five states accounted for most of the latest increase in cases—California, New York, Washington, Minnesota, and North Carolina.

MORSE POSTPONES MEDICAL COSTS PROBE

Sen. Wayne Morse (D., Ore.), who has severely criticized the medical profession in speeches, postponed until next year his proposed investigation of Blue Cross-Blue Shield rates in the District of Columbia. More than a year ago the Oregon lawmaker announced he would hold hearings on the subject, after a rise in rates by Group Hospitalization, Inc., Washington's Blue Cross Plan. After a single hearing he said the staff of his Senate District of Columbia subcommittee would prepare for more extensive hearings on the entire field of medical costs in the district. Recently Senator Morse said the investigation would not begin until after Congress convenes in January.

NEW U. S. FOOD GUIDE EXPOSES DIET QUACKERY

Food and diet experts warned the American public in a government document that hundreds of millions of dollars are wasted every year by overweight persons on quack diets, pills, and gadgets.

Writing in the Agriculture Department's 736-page volume, "Food," an expert declared that 10 million overweight persons waste 500 million dollars annually on "miracle" diets and patent medicines. Helen S. Mitchell, dean of the University of Massachusetts School of Home Economics, said the would-be reducers are ignoring the simple fact that they are supplying their bodies with more food than they can burn up in physical activity.

"The only known cure for overweight is to eat food that furnishes less energy than one needs for body maintenance," said another expert in the volume.

MISCELLANY

U. S. Surgeon General Leroy E. Burney said the type of encephalitis occurring in New Jersey, eastern equine encephalitis, is the least common and most highly fatal of the three known varieties. He said the state's mosquito eradication program should result in a decline in the epidemic, the worst since 34 cases were reported in Massachusetts in 1938.

More than 5 million square miles in the Americas has been freed of malaria, according to a report of the Pan American Health Organization. The delegates to the PAHO's 11th annual meeting here were told that total malaria eradication has been achieved in the U. S., Chile, Puerto Rico, Barbados, and Martinique.

New wide-use dosage form

of this outstanding

anticholinergic-antispasmodic

PRO-BANTHĪNE®

TABLETS

(HALF STRENGTH)

Pro-Banthīne (Half Strength) has been especially designed for your prescribing convenience.

This new form provides flexibility of dosage from low levels of one tablet t.i.d. for patients with minimal distress, to one or two tablets every 2 or 3 hours for those with more pronounced symptoms.

Primary indications are gastrointestinal spasm, bladder spasm, maintenance therapy of peptic ulcer and "irritable bowel" syndrome. The lower dosage also has a field of usefulness in smooth muscle spasm of children and geriatric patients.

when your prescription reads—
℞ Pro-Banthīne Tablets (Half Strength)
—the pharmacist will dispense this new size (7½ mg.)

PRO-BANTHĪNE *(brand of propantheline bromide)*

Dosage forms:
Pro-Banthīne tablets (15 mg.)
Pro-Banthīne tablets (Half Strength) (7½ mg.)
Pro-Banthīne ampuls (30 mg.)

USE AND OVERUSE OF TRANQUILIZERS

Frank Orland, M.D., Camden, N. J.

Tranquilizing drugs render an incalculable service in the hands of the general practitioner as the first line of defense in controlling emotional illness, but their prolonged use is beset with limitations and dangers. In the first of two cases cited here, a 37-year-old man took reserpine for a year to relieve a chronic anxiety state; he then took on additional responsibilities, which led to increasing the dosage. After much damage had been done, psychotherapy at length rendered him symptom-free. In the second case, a 34-year-old man constantly beset by family problems was treated with barbiturates and meprobamate. He became excessively dependent on drugs and was hospitalized twice for severe breakdowns before psychotherapy was instituted for the purpose of correcting the underlying maladjustments. The constant use of tranquilizers over extended periods of time will cause a worsening of the psychiatric symptoms unless caution is exercised.

During the last decade, we have witnessed the advent of a new and powerful group of psychochemotherapeutic agents, popularly described as tranquilizers or ataraxics. Included in this group are such compounds as reserpine, meprobamate, chlorpromazine, and promazine. As pointed out by Fazekas and others,[1] tranquilizers or ataraxics differ from the aliphatic depressants (i. e., barbiturates, chloral hydrate, paraldehyde, and bromides) in that the former do not reduce cerebral oxygen consumption, act at subcortical levels, and do not cause a descending depression of the neuroaxis beginning with the phylogenetically higher centers. Accordingly, Winkelman[2] has suggested substitute terminology for chlorpromazine, such as reticular formation depressant, diencephalic depressant, or ascending depressant. These medicaments have received widespread use by the general practitioner in dealing with mental illness and emotional problems.

There is no doubt that the general practitioner renders an incalculable service as the first line of defense in controlling and managing emotional illness. Without his help, psychiatrists would be overwhelmed and inundated by patients who either do not immediately require psychiatric care or would not benefit from it. Occasionally, however, in the well-intentioned attempt to give a patient continued relief over an extended period of time, important psychological implications and consequences may be overlooked. Dickel and Dixon[3] have emphasized the likelihood of aggravating emotional illness through the use of tranquilizers. The question then arises, if these psychochemo-

---

From the Department of Psychiatry, School of Medicine, University of Pennsylvania.

therapeutic agents are to be utilized effectively by the general practitioner, what limitations and dangers inherent in their prolonged use should be considered?

Use by the General Practitioner

The uses of these drugs for psychiatric problems by the general practitioner to reestablish a psychobiological homeostasis are many and varied. Several of the more prominent indications are aiding the patient over a temporary emotional disturbance due to excessive environmental stresses (for example, tensions in a girl about to be married), controlling the hyperactivity of a psychotic until hospitalization, compensating a mild depressive state, maintaining a mildly disturbed senile patient, reducing transient mild anxiety states, controlling acute alcoholic states, stabilizing chronic alcoholics, and controlling withdrawal symptoms of drug addiction. Needless to say, the type of tranquilizer selected and the dosage utilized are predicated on the patients' needs and clinical responsiveness.

In administering these drugs, it is often more effective to combine use of the medicament with supportive reassurance and suggestions to decrease excessive environmental stress and reduce irrational fears, allowing the patient to ventilate thoughts and feelings, and other techniques which may decrease strains on the personality structure. For example, with a decompensating senile patient, it is of importance to reeducate the family so that they may participate in his successful management. With this type of patient, it is essential to maintain his emotional security, to give him a sense of importance and of being needed, and to increase his feelings of worthiness and personal dignity. This necessitates the interpretation of the patient's problems to those who are responsible for his care and the gaining of their tolerance and active assistance in achieving these goals.

It must be kept in mind that chemotherapy as well as the shock therapies (such as electroshock therapy and insulin shock therapy) do not change the basic personality structure. They compensate a personality which has decompensated, bringing it back to the previous level of functioning prior to the onset of the emotional disturbance. Therefore, the use of these drugs alone is a doubtful procedure where the patient has the type of personality structure and the motivation to benefit from psychotherapy. In this situation, tranquilizers, if used at all, serve best as an adjunct to psychotherapy. As Guartney and associates[4] have pointed out, tranquilizers provide temporary relief at best, and what is usually needed is psychotherapy.

Psychiatric Consequences of Prolonged Use of Tranquilizers

In quite a few patients, despite the heroic attempts at tranquilization over an extended period of time, the personality continues to decompensate, new psychiatric symptomatology emerges, and the entire reality situation becomes worse. What may occur psychiatrically with the continued prolonged use of tranquilizers?

Prolonged administration of tranquilizers may decrease tensions to such a degree that the patient becomes oblivious to the realities of life. A certain minimum level of anxiety is a prerequisite for psychobiological survival since it makes one aware of existing problems and furnishes motivation to seek their solution. If an oversuppression of anxiety occurs, it may eventually lead to greater pathological symptoms than the original symptom complex. The patient no longer has any worries, no longer plans logically, tends to make impulsive decisions, may manifest defective reasoning and judgment, and as a result may find himself in real difficulties. These will create further problems with their associated anxieties and tensions, necessitating increasing dosages of the tranquilizer to mask it. Thus, a vicious cycle is established in which the patient continues to decompensate clinically. The following case illustrates this.

Case 1.—This 37-year-old man came into treatment with a mixed anxiety and depressive state. For the preceding three months, he had been experiencing increasing episodes of crying with associated feelings of helplessness and despair, insomnia, anorexia, generalized tension, restlessness, and anxiety. Because of this, he was in danger of losing his job.

His medical history revealed that he had had rheumatic fever as a child, with consequent rheumatic heart disease, for which the Army had rejected him. However, he had always been cardiologically compensated without resorting to medicaments. In 1953, radiology disclosed a healed duodenal ulcer; since this date the patient had been intermittently treated for "nerves" by various physicians.

His personality history revealed a chronic anxiety state, hyperactivity, strong tendencies toward exactitude, perfectionism, and extreme neatness. Family history revealed that the father (who was an aggressive salesman) separated from the mother (who was a chronic worrier, hypochondriacal, and over-protective of the patient) when the patient was 15 years old. He then lived with his mother and grandmother until he was 27, when he married. After this, his mother and father reunited.

The present illness was precipitated three months previously when he was advised to suddenly discontinue use of reserpine, which he had been taking for the preceding year. For that year the patient had been on reserpine therapy for anxieties and tensions resulting presumably from increased occupational stresses. At first, he felt relaxed, his apprehensiveness lessened, and he felt buoyant. He took on greater responsibilities at work and developed anxieties and tensions again, but he covered these over with increasing dosages of the medicament. He then became listless, lost interest in social activities, became impulsive in his actions, and began using defective judgment in handling his personal affairs. He depleted his bank account of about $3,000 and went into debt for about the same amount through unnecessary purchases of a new car and new furniture. As a result of these reality problems he developed marked anxiety, but again an attempt was made to cover it through increased use of medicaments. This time no relief was gained, and he continued to decompensate psychiatrically. He was then seen once weekly in psychotherapy for a period of six months, at the end of which time he was symptom-free and was taking no medicaments. Information received three years later indicated that he was doing well.

Comment.—The above case indicates the importance of constantly reevaluating the patient's behavior patterns in present life situations when these drugs are being administrated. Prolonged administration of tranquilizers tends to fortify the patient's misconceptions that the causative factors are organic rather than functional. If the functional aspects are not emphasized, the development of an iatrogenic organic neurosis may be fostered. This tends to serve as a barrier or resistance toward facing and dealing with emotional conflicts. If the medicament fails to alleviate the somatic symptomatology, both patient and physician become frustrated and discouraged. It is therefore highly advisable to emphasize the functional components in the etiology of the symptoms and the temporary nature of the help given by tranquilizers.

There are a group of patients whose personalities require that they maintain complete control over their environment to achieve emotional security. Excessive tranquilization may lead to increasingly ineffective efforts in this direction due to diminution of energies and impairment of ego functions (reasoning, judgment, and apperception). Consequently, there is further emotional insecurity and an increase in symptomatology. Tranquilization is then increased to cover this, and a vicious cycle is established leading to increased personality decompensations. Therefore, with this group of persons, caution should be exercised regarding the intensity of dosage.

Prolonged administration of tranquilizers may foster undue dependency on both the medicaments and the physician. Patients often wish for the "magic pill"—an omnipotent potion which is swallowed and painlessly relieves their emotional turmoil. Their wish is for something to be done to them so they can sit passively without putting out any effort in getting well, acting almost as a disinterested third party (as in receiving an injection of penicillin). However, this attitude diverts the patient's efforts from realistic problems in his life situation and from the emotional conflicts within himself which created the symptoms. This dependency may lead to increased feelings of inadequacy and helplessness, resulting in increased need for the medicament, and deeper dependency. Thus, a vicious downward cycle may be initiated with possible habituation to the drug. Emotional conflicts are perpetuated rather than resolved. The psychopathology is masked but continues to cause maladaptation, maladjustment, and clinical symptoms. The possibility of addiction to the medicament must also be considered as part of increased dependency on the drug. Stough,[3] in a study on meprobamate, concluded that no habituating properties were demonstrable. However, the following case indicates that habituation may occur.

Case 2.—This 34-year-old man had had chronic anxiety and tensions since 1946. Family history revealed that the father had died when the child was 16 months old; the child was raised by an alcoholic mother. At the age of 24 years, he married a dominant, aggressive woman who ruled him at her will.

From 1946 through 1956, he was treated with barbiturates for daytime sedation and sleep. As his family increased, more tensions developed, and meprobamate therapy was started in 1956. Not only were his tensions relieved, but he experienced a mild euphoria and exhilaration. However, he became more inadequate at home, felt more helpless in his relationship with his wife, and proceeded to cover these feelings by increasing his meprobamate dosage. Soon he was taking 16 400-mg. tablets of meprobamate a day. He became confused and befuddled at work, made numerous errors, and job loss was threatening.

He was admitted to a psychiatric hospital, where they immediately deprived him of all meprobamate. This caused withdrawal symptoms of nausea, vomiting, muscular tremors, depression, and one convulsion, all within a period of 24 hours. He felt fine the next day and was discharged in three weeks. He was placed on meprobamate therapy again, and the same cycle ensued. He was rehospitalized and this time the drug was withdrawn gradually. He also received seven electroshock treatments. Within one month after discharge he was rehospitalized for secobarbital intoxication.

It was at this point that he came into psychotherapy. He has not been rehospitalized and at present is maintained on 400 mg. of meprobamate four times daily. Thus, excessive dependency on the physician and habituation to the drug may be a consequence of prolonged administration of a tranquilizer.

Summary and Conclusions

The general practitioner is the first line of defense in managing and controlling mental and emotional illnesses. Tranquilizers do not resolve emotional conflicts but may restore a personality to its previous functioning level or to psychobiological homeostasis in indicated situations. Prolonged or excessive use of tranquilizers should be undertaken with caution as it may lead to an increase in psychiatric symptomatology, excessive dependency on physician or medication, fixation on an organic etiology, defective management of daily affairs, or to a denial of emotional problems. Constant reevaluation of the patient's psychiatric symptomatology and handling of reality situations is indicated when a tranquilizer is administered over an extended period of time.

A RESIDENCY IN RADIATION THERAPY

John O. Archambeau, M.D.
and
Orliss Wildermuth, M.D., Seattle

Radiation therapy has not received the consideration it deserves from the physician evaluating the various specialties prior to selecting one for his residency training. This is so because few recognize that radiation therapy exists as a separate specialty in the practice of medicine. It is thought of as only one facet of radiology and is not considered further. While in a sense it is a part of radiology, actually there is a separate certification in radiation therapy issued by the American Board of Radiology. Qualification for examination for certification follows a training period of three years devoted to the arts and sciences of the application of ionizing radiations in the management and treatment of patients with cancer. A fourth year is devoted to practice or further training. The rationale for the separation of the two branches of general radiology and its evolution is thoroughly discussed by Newell[1] and others. Briefly, it is felt that a full knowledge of radiation therapy cannot be obtained from the present training program in general radiology.

Those specifically interested in the cancer problem should note that radiation therapy is primarily concerned with the frustrations attendant to cancer treatment and investigation. Radiation therapy, then, is a clinical specialty, and the therapist is a clinician. Unhappily, it has often been considered as merely a technical service to be administered by someone who understands the production of x-rays but has little knowledge or interest in the problems of cancer patients and the diagnosis and management of their disease. Fortunately this is an anachronism. In certain areas, however, a pioneering spirit is still needed to overcome apathy and habit.

At present radiation therapy is in a vigorous growth period. Supervoltage machines, rotational therapy, and radioisotopes have increased its versatility and applications. Until a breakthrough occurs in the treatment of cancer, we can expect continued growth and usefulness of radiation therapy. It is an uncrowded specialty, with only about 100 full-time practicing clinical therapists. The need for therapists far exceeds their availability, and this lopsided situation is expected to continue.

Residencies in radiation therapy as such do exist. They are to be found in departments and institutions devoted only to radiation therapy, as well as in departments of radiology which will permit the single emphasis in therapy. Admittedly there are few, but the situation is changing. Unlike in many residencies, the grim aspect of financing the training years is diminished because residents in radiation therapy are eligible for training fellowships from the National Cancer Institute and the American Cancer Society.

Function of the Radiation Therapist

What, then, can a resident expect of radiation therapy, and what is the function of the therapist in a department devoted solely to radiation therapy?

As any consultant, the therapist has his own obligations and prerogatives. He is not running a "prescription service." He knows better the capabilities of his therapeutic armament than the referring doctor. The patient is seen on referral or for initial examination if self-referred. A history and physical examination are completed; all records and reports are accumulated and studied; diagnostic and investigative procedures are carried out; and the histology is reviewed. This underscores the necessity of

---

Fellow, National Cancer Institute (Dr. Archambeau), and Associate Director (Dr. Wildermuth), Tumor Institute of the Swedish Hospital.

determining or confirming the diagnosis and extent of the lesion. Then—and only then—is it ascertained whether radiation therapy should be used and, if so, whether in preference to or in combination with surgery or chemotherapy. If radiation therapy is elected, the type, whether curative or palliative, the dose to be given, and the method of protraction are decided and therapy is initiated. It must be remembered that when radiation therapy is utilized it is an expensive, time-consuming course not without hazard to the patient and requiring careful control to achieve the best results even in palliation.

During the treatment period the management of the disease and the care of the patient, whether as outpatient or hospital patient, is under the supervision and guidance of the therapist. A considerable amount of the therapist's time is spent in the therapy suite supervising the treatment of the patients under his care. This includes setting up new treatment fields and following the treatment that is already in progress for some patients. It is here that one observes the course of the patient and adjusts the treatment plan to the patient. Here complications and reactions are to be observed and cared for. Questions are answered; complaints are evaluated and explained; and psychic support is given always.

After completion of radiation therapy, the patient is not "lost to follow up." He returns periodically to the follow-up clinic for continued observation and management. Long-term follow-up is necessary in order that results can be evaluated and possible complications treated. In this way future treatment programs can, if necessary, be revised, and with continued known good results the application of radiation therapy can be widened.

Aside from having special knowledge of x-ray production and utilization, the therapist must be well acquainted with clinical diagnostic techniques. In evaluating his patients he uses the general examining methods common to all physicians. He must be efficient with the laryngeal and nasopharyngeal mirror, the anoscope, and the proctoscope. He must be expert in regional examinations of the pelvis, abdomen, chest, and nasopharynx. In caring for his patients he often must manage the disease through the terminal phase by judicious use of drugs, fluids, and supportive care.

The modern therapist depends on a close working rapport with various specialties and services. Diagnostic x-rays will be needed, as will biopsies, bronchoscopies, crystoscopies, direct laryngoscopies, etc. Some patients may need surgical procedures prior to treatment or after. It must be emphasized that the therapist is not working in competition with other specialists but in association with them. This association will be rewarding to both the patient and the therapist, because the eclectic process assures the patient of the best therapy and brings new ideas and techniques to the attention of the attending physicians.

Probably one of the most penetrating contacts with other specialties will be that with pathology. The surgical pathological slides must be reviewed and studied separately and then discussed with the pathologist. The therapist must know and appreciate the morphology and histology of the cancers and tissues he treats. He has to know the natural history and radiobiology of cancers and of normal tissues. Because of its importance, a period—usually six months—of the resident's program is spent in pathology. During this time the problems of histology, ecology, and natural history of cancer are introduced by the performance of postmortem examinations and study of surgical specimens. This does not make him a pathologist, but it provides an introduction to the lifelong association the therapist will have with the vagaries of cancer.

Machinery and Principles in Radiation Therapy

Exact physical foundations underlie the machinery and principles used in radiation therapy. A certain minimum knowledge of physics is required. The therapist's contact with physics is on a daily basis, and from this constant exposure he becomes familiar with the necessary principles. Of course there is room for more sophisticated knowledge of physics for individuals with the ability and background. In addition, there is available in the complete department a physicist with whom one can consult when there are perplexing problems of dosimetry and dose. The supervoltage units, with their energy in the millions of electron volts, have increased depth dose and tissue-sparing qualities not yet fully appreciated and awaiting further clinical observation, use, and understanding. Of necessity this demands the clinical guidance of the therapist along with the logistic, technical, and quantitative support of the physicist. During his residency the therapist must have the opportunity of attending lectures on radiation physics. These will give him the foundation for understanding the physical side of his specialty and the relationships between ionizing radiations, energy transfer, and biology.

Often the radiotherapist is called on to direct and supervise the use of radioisotopes. Because of his training and experience with radioactive materials, the therapist is well suited to the job. This follows, since much of the early development of the specialty evolved from the use of radium, and at present intracavitary and tissue implantation of radium is well entrenched in the therapist's armamentarium. Of recent evolution is the widespread use of radioactive cobalt (Co^{60}) in teletherapy units.

Aside from the laboratory and investigational use of radioisotopes, nuclear medicine has provided definite therapeutic applications. Some examples are radiophosphorus in the treatment of leukemia and polycythemia; radiogold and chromic phosphate for intracavitary administration and tissue injection; and, of course, radioiodine for carcinoma of the thyroid. The laboratory and diagnostic possibilities touch on all facets of biology and medicine from cellular metabolism to the localization of tumors; therefore, ample opportunity is provided in the training program to learn the diagnostic and therapeutic techniques indicated.

The clinical side of radiation therapy, permitting abundant and rewarding patient contact, has been emphasized. For those with a research inclination radiation therapy through its disciplines and orientation lends itself well to investigation either in the field of cancer or in radiobiology. The spectrum of problems available ranges from epidemiologic to physical and from clinical to basic. In radiobiology there is a demand to correlate radiochemical events and cellular physiology. It must be stressed that the cancer problem is unsolved; a multitude of opportunities are available; and limitations are decided only by the individual's ingenuity and ability.

By emphasizing that radiation therapy exists as a separate specialty practice of medicine and outlining the scope of the present-day radiotherapist, we have tried in this article to assist the interested physician—particularly the prospective resident—in his evaluation of the specialty.

TERATOGENIC EFFECTS OF ASIAN INFLUENZA

Miriam G. Wilson, M.D., Henry L. Heins, M.D., David T. Imagawa, Ph.D.
and
John M. Adams, M.D., Los Angeles

That a cause and effect relationship exists between a maternal viral infection during the first trimester of pregnancy and congenital defects in the child remains inconclusive, except in rubella, since most of the studies are of a retrospective type. Introduction of Asian influenza into our population afforded conditions for study of this possible relationship with a greater measure of control and more factors known prior to birth of the infants. In March, April, and May of 1958, hemagglutination-inhibition titers for Asian influenza were determined on 126 expectant mothers whose last menstrual periods occurred in October, November, and December of 1957. Mothers (75) having positive titers were considered to have had influenza and were compared with those (51) having negative results. The two groups of mothers did not differ significantly with respect to the incidence of anomalies among the children delivered, and no definite evidence of a teratogenic effect of Asian influenza virus was found.

The effect of maternal viral infections on the developing embryo has been a subject of interest since Gregg's original observation of the teratogenic effect of rubella.[1] Viruses, other than that in rubella, have not been strongly incriminated as teratogenic agents, although some evidence exists that mumps, influenza, rubeola, varicella, and poliomyelitis may cause anomalies in the human embryo.[2] Other studies indicate that maternal infections with rubeola, poliomyelitis, varicella, and variola may result in termination of pregnancy or neonatal infection but rarely, if ever, in congenital anomalies.[2a] Conclusions are difficult since most studies are retrospective in type, consisting of evaluation of the maternal histories of deformed infants and, therefore, without a completely satisfactory control group for comparison. A recent prospective study[3] has shown that there is a tendency for acute febrile illnesses early in pregnancy to be associated with fetal abnormalities, but neither the type of illness nor the fetal abnormality could be further specified.

The recent exposure of the population to the previously unencountered Asian strain of influenza A virus stimulated the present effort to determine whether any increased incidence of congenital anomalies resulted from maternal Asian influenza.

From the departments of pediatrics and infectious diseases, University of California at Los Angeles.

Experimental data of Hamburger and Habel,[4] and later of Adams and others,[5] demonstrated that human influenza viruses, when introduced into the early chick embryo, resulted in deformities. Mice inoculated with influenza at the time of mating had increased numbers of fetal abnormalities as well as a decreased pregnancy rate.[5b]

Walker and McKee,[6] studying a group of mothers whose early pregnancy coincided with the Asian influenza epidemic in their area, found an incidence of 3.3% major anomalies within the group and concluded that Asian influenza was not associated with an increased risk of abnormal offspring.

In order to determine the effect of maternal Asian influenza on congenital anomalies among the offspring, the incidence and type of deformities in newborn infants from mothers with known Asian influenza titers (hemagglutination inhibition) were studied nine months after Asian influenza became evident in the Los Angeles County area. Any significant difference in anomalies in newborn infants from mothers with elevated titers as compared with those mothers with negative titers would tend to indicate that maternal Asian influenza influences fetal development.

TABLE 1.—*Hemagglutination-Inhibition Titers from Los Angeles County Prenatal Patients during March, April, and May, 1958*

Titer	Patients, No.
Negative	180
Positive

1:10	47
1:15	72
1:20	120
1:30	54
1:40	57
1:60	13
1:80	14
1:160	4
1:320	1
Total positive	558
Total positive and negative	738

Method of Study

During March, April, and May, 1958, single blood specimens were drawn from Los Angeles County prenatal registrants whose latest menstruation dated conception during October, November, or December, 1957—the period in which an epidemic of Asian influenza was first recognized in Los Angeles.[7] All the selected women planned to deliver at Los Angeles County Hospital.

Hemagglutination-inhibition (HI) titers were determined by use of the procedure described by Salk.[8] The hemagglutination antigen used throughout this study was pooled allantoic fluid influenza A/Asian/Japan/305/57. Each serum sample was treated with periodate before testing.[9]

Since blood specimens were drawn throughout the second trimester of pregnancy, a few mothers with influenza contact after the first trimester may have been included. Other limitations resulting from the availability of only one blood specimen were also present. Infection could have occurred before the first trimester in a few women who retained a positive antibody titer for four months or longer. Nonspecific titer elevations were felt to be less significant since the population had not previously been exposed to the virus of Asian influenza.

TABLE 2.—*Association of* [illegible] *with History of "Flu-like* [illegible]

Symptoms	Titers Neg.	1:5	1:15	1:20	1:30	1:40	1:60	1:80	Total
Influenza	18	2	2	7	5	5	..	1	40

Total	51	11	8	25	14	12	2	3	126

Newborn infants from mothers with positive HI titers (experimental group) and from mothers with negative HI titers (control group) were studied. A single pediatric resident assigned under the supervision of a qualified pediatrician interviewed all obstetric admissions from the control group and experimental group and examined all infants born to these mothers. Individual patient titers were unknown to either the pediatric resident or the pediatrician.

TABLE 3.—*Maternal Hemagglutination-Inhibition Titer Related to Characteristics of Infants*

Total	51	12	7	25	13	13	2	3	126

* Twins tabulated as one birth.

Congenital anomalies of a major type were included in the study, according to the suggestions of Davis and Potter.[10] Minor conditions such as nevus flammeus, undescended testes, mongolian blue spots, skin tags, hydroceles, and umbilical hernias were not included.

Results

HI titers were obtained from 738 pregnant women in the prenatal clinics. From this number, a list of 377 was selected by including highest titer-reacting and negative titer-reacting women reasonably certain of delivering at Los Angeles County Hospital. A final total of 126 mothers were interviewed at Los Angeles County Hospital. The infants born to these mothers were examined in the nursery. The relatively small number seen in the hospital was due to a number of factors, such as changes in delivery plans, surname changes, and failure of notification by the admission office that a study mother had been admitted.

TABLE 4.—*Maternal Titer Related to Characteristics of Infants*

Maternal Titer	Total No.	Abnormalities, Including Twins* and Stillbirths		Abnormalities, Excluding Twins* and Normal Stillbirths		Normal Prematures, Excluding Twins and Stillbirths		All Prematures	
		No.	%	No.	%	No.	%	No.	%
Negative Titer	51	4	7.8	2†	3.9	2	3.9	5	9.8
Positive Titer	75	4	5.3	2‡	2.7	4	5.3	7	9.3
Total	126	8	6.3	4	3.2	6	4.8	12	9.5

* Twins counted as one pregnancy product.
† One familial cleft palate; one possible amyotonia.
‡ Anencephaly

The distribution of HI titers for Asian influenza obtained from the prenatal patients is listed in table 1. It was of interest to determine how well influenza titers correlated with the history of influenza, influenza-like symptoms, or close contact with influenza in the absence of illness. For this purpose influenza was arbitrarily defined as (1) fever, myalgia or headache, and sore throat or cough or (2) influenza diagnosed by a doctor. It is apparent from table 2 that history of illness showed only a chance relationship to influenza titer. Physician-diagnosed influenza as well was not significantly related to titer. No characteristic of the history of illness, including the time period in which the illness occurred, was related to the obtained titer values. The usual difficulties in obtaining retrospective histories of illness and symptoms must be kept in mind.

TABLE 5.—*Complications of Maternal Pregnancy for Four Infants with Anomalies*

Infant					
Sex	Weight, Gm.	Anomaly	Illness in First Trimester	Other Abnormality of Pregnancy	HI Titer (Maternal)
M	2,100	Cleft palate	None	None	Negative
M	4,000	Amyotonia (?)	None	None	Negative
F	1,300	Anencephaly	Cough, sore throat and fever for three days	None	1:20
F	1,670	Anencephaly	Coryza and cough for four days	Polyhydramnios	1:5

The outcome of pregnancy in the mothers in the study is summarized in tables 3 and 4. The incidence of abnormalities, including twin births and stillbirth, in the total group was 6.3%. Twin births are counted as one abnormality. Six of the eight abnormal births were also premature. Excluding twin births and otherwise normal stillbirths, the incidence of gross congenital anomalies was 3%.

The incidence of abnormal births and of congenital anomalies did not differ significantly in the experimental as compared with the control group. Within the group of mothers with positive titers, higher titers were not related to an increased incidence of birth abnormalities, including congenital anomalies.

A prematurity rate of 9.5% was found for the combined total group. The incidence of prematurity at Los Angeles County Hospital was 11.2% in 1956 and 12.6% in 1957. Although the 1958 rate is not as yet available, the prematurity rate does not appear to have been adversely affected by Asian influenza in this area. Mothers with negative titers did not differ significantly in incidence of prematurity from those with positive titers.

The congenital anomalies were anencephaly in two infants, cleft palate in one, and generalized hypotonia in one. The latter infant was given a diagnosis of possible amyotonia, but without diagnostic clarification by follow-up visits. The infant with a cleft palate had a sibling with the same anomaly, and so there remains the possibility of a genetic background. Anencephaly, occurring twice in the small group sampled, was found on both occasions in infants born to mothers with positive, although relatively low, titers. The mothers of the anencephalic infants gave a history of a "cold" in the third month of pregnancy, associated with a three-day fever in one (1:20 titer) and unassociated with systemic symptoms in the other (1:5 titer). Maternal and family characteristics of the infants with congenital anomalies are found in tables 5 and 6.

TABLE 6.—*Family Characteristics of Four Infants with Congenital Anomalies*

Anomaly	Age		Maternal Gravidity	Abnormal Previous Pregnancies	Family Anomalies
	Maternal	Paternal			
Cleft palate	37	40	11	3 premature 1 spontaneous abortion	Cleft palate in one sibling
Amyotonia (?)	18	23	3	None	None
Anencephaly	20	24	2	None	None
Anencephaly	22	26	2	None	None

The control and experimental groups did not differ in neonatal morbidity and mortality rates, or in incidence of macrosomatia (weight greater than 4,550 Gm. [10 lb.]), dysmaturity, physiological jaundice, or hemolytic disease of the newborn. One infant of each group had a questionably significant murmur which disappeared on later examination and remained unassociated with signs of cardiac disease.

Summary

No significant teratogenic effect of Asian influenza was demonstrated in a study in which newborn infants of mothers with positive hemagglutination-inhibition (HI) titers were compared with infants of mothers with negative titers. However, of the two infants with congenital anomalies found in the control group, one with a cleft palate possibly had a genetic background for the anomaly and the other had only a presumptive diagnosis of amyotonia. The only other congenital anomaly, anencephaly, was found in two infants of the experimental group. Only speculation is possible regarding the significance of this occurrence.

This study has been aided in part by grants from the United Cerebral Palsy Research and Educational Foundation and from the National Institutes of Health, U. S. Public Health Service; it has been made possible through the cooperation of the Los Angeles County Health Department and the Los Angeles County Hospital.

PEDIATRICS IN THE SPACE AGE

Wyman C. C. Cole Sr., Detroit

Those of us who can still remember the horse and buggy days, who have succeeded in living through the automotive age, and who have taken the atomic and jet ages in stride can hardly refrain from speculating on the future of pediatrics in the space age, which we are now entering. What advances will there be in the science of pediatrics? What changes will there be in the practice of pediatrics?

A Backward Look

Perhaps we can get a better perspective of what lies ahead by looking backward. At the turn of the last century, if someone had said that in 1959 it would be relatively simple to have breakfast in Paris, lunch in New York, and a round of golf in Miami all in the same day, we would have said that he was out of touch with reality. We probably would have called for the wagon and the men in the white coats. It is no more fantastic to assume that at the next turn of the century we will be spending week-ends on Mars and spending our summer vacations on Venus.

Changes in both the science and the practice of medicine since the beginning of the century have been equally dramatic. Diseases which were considered inevitable have disappeared. Surgical procedures beyond the flight of fancy are now routine. Drugs, which we still call miracle, are in every physician's bag. Moreover, there is every reason to believe that this is only the beginning.

Chairman's address, read before the Section on Pediatrics at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 9, 1959.

It is just 40 years since the end of World War I, when I began to practice pediatrics. At that time the pediatrician was chiefly occupied with the treatment of sick children and what was called infant feeding. Little attention was paid to growth and development and even less to mental hygiene and the emotional problems of children. Vitamins were still in the laboratory stage. Vaccination for smallpox was the only routine immunizing procedure.

A farseeing prophet in 1919 could have said to a young man entering practice: "If you are still practicing in 1959, here are some interesting facts: 1. You will not have seen a clinical case of diphtheria or tetanus for 25 years. 2. A suitable formula for 99 out of 100 babies can be purchased in a can at any drug store or supermarket. 3. Rickets, scurvy, and infantile tetany will be textbook diseases that you will rarely, if ever, see in private practice. 4. It will be at least 15 years since you have seen a patient with surgical mastoiditis. 5. Most cases of pneumonia and scarlet fever will be treated in your office and will be essentially cured in 24 hours. 6. Very few babies will die of diarrhea because of what you have learned about electrolyte and water metabolism."

The young man might have answered that he could see little sense in going into pediatrics, since all the major problems will soon be solved. This is reminiscent of the well-known professor of physics at one of our major universities, who in the year 1894 advised his students not to go into physics as all essential facts were known. If he came back today, it would take him a little while to catch up on his homework.

A Forward Look

All science, of which medicine is a major segment, is like the multiheaded hydra. Each time one problem is solved, two new ones arise to take its place. Each discovery, while answering some old question, broadens our horizon so that we constantly see new and more complex problems. An excellent example of this is the recent discovery of the steroids, which has opened up fields of investigation that will take decades to explore. The more we learn, the more is seen that we do not understand.

As for pediatrics, instead of disappearing, both the science and the practice have increased a hundredfold. If the same prophet could again make his predictions in 1959 as to what medicine will be like 40 years hence, perhaps he could say: "1. Cancer and leukemia will have been relegated to medical history. 2. The 'common cold' will have been forgotten. 3. Babies will rarely be born prematurely. 4. A simple explanation and method of control will have been found for allergy. 5. A single injection or pill will immunize children against all of the communicable diseases. 6. Many congenital defects will be avoided by a better understanding of genetics. 7. Such metabolic diseases as diabetes, arthritis, and cystic fibrosis will be easily controlled by improved knowledge of the enzyme system."

I am sure this is only a small fraction of what will actually transpire. Where will pediatrics fit into this framework of ever accelerating progress? Surely no one will question that, in spite of phenomenal advances, the science of pediatrics is still in its infancy. Each month our journals are bulging with the reports of significant investigation. Hundreds of bright young men are dedicating their lives to this field of endeavor.

Attitudes in Pediatrics

Recently, however, there have been rumblings that the practice of pediatrics is on the decline. Various allegations have been made: 1. The newer pediatrics does not lend itself to everyday practice. 2. Pediatric diagnosis and treatment are either so complex that they require highly specialized institutional care or so simple that they can be handled by any general practitioner. 3. Pediatric practice is uninteresting and boring because so much of it is routine and monotonous.

With this I do not concur. Those who entertain these views have about the same foresight as the previously mentioned physics professor. Of what value is medical progress if it is not applicable to the everyday care and welfare of the patient. The science of medicine is useless except as it improves the practice. I cannot believe that anything of real merit is beyond the comprehension of the average physician or his ability to apply it.

I do not understand what is meant by "the newer pediatrics." If we mean exact diagnosis and definitive management in the fields of cardiology, metabolism, hematology, and endocrinology, no one can be competent in all of these areas. But this is not the practice of pediatrics. The practitioner must have enough knowledge of these subjects to recognize them and consult with, or refer them to, appropriate authority. This is the function of the hospital, the clinic, or the teaching center. These facilities occupy the same relation to the practitioner as do the roentgenologist or the clinical laboratory. These subspecialists are comparable to technicians, who are called in to do a special job. It constitutes a very minor part of daily practice.

Those who find pediatrics monotonous and boring are practicing with their eyes shut. They are lacking in awareness of what pediatrics is. They are miscast and should be in some other type of work. Of the thousands of times I have discussed with a young mother her perfectly normal baby, I have never once found it boring. She may have memorized Dr. Spock's excellent book from cover to cover, but she needs something more, the personal touch. It is gratifying to feel that you are giving this mother confidence and starting a new family off in the right direction. It is not as dramatic as a cardiac catheterization, but it is more basic and in the long run more important.

Pediatrics has never been a specialty in the strict sense. It is general practice confined to an age group. It is impossible to practice competent pediatrics without sound grounding in almost every field of medicine. There has sometimes been a tendency for the specialist to look with condescension on the general practitioner. I suspect that those who, looking down from their ivory tower, question whether the "newer pediatrics" can be practiced, fall in this category. This is wrong. Almost anyone of normal intelligence can become an expert in a given field if he devotes his whole time to it, but to become a good general practitioner requires not only broad knowledge but also strength of character and a deep understanding of human relations. When Mrs. Smith's child is taken sick on Saturday night she does not want an appointment with the hematologist on Monday morning; she wants a doctor and she wants him now.

Influence of the Pediatrician

Our present resident-training programs teach the young physician much about disease. Unfortunately few of them teach him much about how to be a physician, which is something entirely different. This he must learn for himself, if he can, often the hard way. Some of the dissatisfaction of younger pediatricians with private practice is due to this. It is a major defect in our training program. We must think of the pediatrician as the child's physician, not merely as one who treats the diseases of childhood. For this I can see nothing but a constantly expanding need.

The revolutionary advance in science in this century has greatly modified our environment but has done little to change the human race. Advance in technology has not lessened but rather increased the political and economic tensions between nations. We are no nearer universal peace than ever. Intolerance, prejudice, and bigotry shown no sign of regression. Likewise, progress in medical science, while doing much to conserve and prolong life, has done little to make life better. In fact, we have failed miserably in this regard as witness the disgraceful incidence of divorce, the steady rise of juvenile delinquency, the appalling amount of mental illness, and the general deterioration of the American home. Responsibility for this state of affairs lies in many areas, but the role of medicine is most important.

The pediatrician is in a unique position to exert a powerful influence. He sees life from its beginning. He can do much to guide the mental and emotional development of the child. More than other physicians he is likely to see parents as they really are and be able to recognize and advise on family problems. Juvenile delinquency is not a problem of adolescence but has its inception in earliest life. Many of the emotional and psychiatric problems of adult life stem from a disturbed childhood. Here lies a challenge to pediatrics which is now poorly met. We will fail in our mission as physicians if we do not rise to it. If there is a "newer pediatrics," this is it. The technical achievements of the space age will not be worth much unless the human race makes somewhere near parallel progress.

The only serious uncertainty about the future of the practice of pediatrics has nothing to do with medicine but arises from the changing economic and political climate of our society. What has been a creeping socialization of medicine has developed into a vigorous crawl. The federal government is considering taking over all hospitalization insurance. Group practice and closed-panel practice on a contractual basis are growing steadily. Even Blue Shield, "the doctor's plan" of prepaid medical care, is becoming more and more inclusive. In some areas it threatens to outsocialize the socialists. Third-party intrusion into the patient-physician relationship is disturbing.

The areas of medicine that are largely technical or that deal with the treatment of acute disease may lend themselves to this type of practice, but it is difficult to see how pediatrics can be practiced in any such framework. Pediatric service is not a commodity that can be purchased over the counter like a pound of coffee. Pediatrics does not lend itself to production-line methods. In no other field of medicine is the personal element so important. Somehow in the changing social order this relationship must be not only preserved but furthered. This is something that we must fight for, not to preserve the private practice of medicine but for the welfare of children.

Where then will pediatrics go in this space age? There can be little doubt that the science of pediatrics will be a component of the same rocket that will carry all science to new and unexplored heights. Since the purpose of this rocket is to transport a useful pay load, it is obvious that the practice of pediatrics will of necessity be in the nose cone.

MEDICINE AND THE LAW—RETROSPECT AND PROSPECT

LeMoyne Snyder, M.D., Paradise, Calif.

The administration of justice in cases involving medical questions is hampered by indifference to the subject of medical jurisprudence in medical schools and by persistence of medieval notions on medical subjects among legislators and jurists. Ignorance of the effects of psychic trauma and organic brain disease still confuses every discussion of criminal responsibility, and anachronistic laws still result in flagrant injustices. A recent case illustrates the impossibility of predicting whether a psychiatrist will report that the accused knew the difference between right and wrong at the time of the alleged crime. In one experiment involving the employees of 16 chain stores a program involving the use of a polygraph reduced the number of admitted cases of dishonesty from 76% to 4%. Science has provided the tools for a vast improvement in the understanding and control of human behavior. These tools should be used to insure fairness in the treatment of mentally sick people, and it is up to society, including the medical profession, to make sure that they are used.

Across the façade of a new western courthouse is carved this inscription, "For what is so important as the administration of justice?" When Alexander Hamilton wrote these words nearly two centuries ago he could not have foreseen the enormous role that medical science was to assume in the judicial process. At that time legal medicine was in its infancy and the tools it had to work with were few and uncertain.

With respect to the history of this subject, while Galen wrote a treatise on simulation and malingering in the second century, there is no record that such knowledge was ever applied by doctors in court. Actually, legal medicine is a very late product of civilization.

One of the first treatises in English on medical jurisprudence was written in 1788 by Farr, who undertook to define it in these terms: "It is a kind of medical knowledge which is not so much concerned in the cure of disease as in the detection of error and the conviction of guilt." Many years later another author expressed the thought more clearly: "Medical jurisprudence or legal or forensic medicine, as it is sometimes called, may be defined to be the science which applies the knowledge of medicine to the requirements of law."

For four centuries prior to the time that colonists from Britain and Western Europe started to settle in North America in the 17th century, the English people had been struggling for democratic government and particularly toward establishing the rights of the individual as against the imperialism of the state. Subsequently, when in large measure the English legal system was adopted in the colonies and the common law became the backbone of our judicial processes, we inherited from Great Britain laws conspicuous for the absence of provisions to apply medical knowledge to the administration of justice. In large measure our laws continue to be hostile to medical jurisprudence. Britain during the 19th century made great advances in this field and established chairs of legal medicine in all its leading medical schools. However, in the United States, in only a few places have the states yet made any demand for competent medical experts to come to the aid of the law.

From the English we inherited the coroner system of medicolegal examinations, and in most parts of the United States the coroner is still the official who is entrusted with that important function. Possessing neither medical nor legal knowledge, which would seem to be a basic requirement, this official survives solely on political popularity—a qualification which a real medical expert is not likely to possess. Oddly enough, the office of coroner is not a product of the political turmoil and Renaissance in England but has survived almost unchanged from the monarchy of the Middle Ages before the days of the Magna Charta and the crusades.

Another adjunct of this system is the outmoded and antiquated coroner's inquest—a tribunal in which a jury of six persons is charged with the determination of the cause of death and naming the person responsible. Generally the first six persons on the nearest park bench are chosen and they take a quick glance at the remains through an open door and listen to what evidence the coroner has at hand. This procedure seems to be founded on the theory that ignorance multiplied by six equals intelligence.

The leading author on medical jurisprudence in the United States a century ago, Dr. Stanford Emerson Chaillé, pointed out that legal medicine owes its power to knowledge derived from every branch of the science of medicine, but the law determines how far that power should be utilized in the administration of justice. Consequently, the development of medical jurisprudence has varied in different nations with the progress of medical

---

Read before the Section on Preventive Medicine at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 10, 1959.

science and with the extent of its application to the protection of life, reputation, and property. Efficiency in the legal application varies with the appreciation of medical knowledge by the rulers of a nation. This resulted in the fact that the law is more favorable to the development of legal medicine in nations which were ruled by the educated few than in democracies, where sovereignty is derived from the people.

Even today we are confronted with numerous examples of purely scientific matters being decided by public forums and political processes. For instance, consider the common situation in which a city wants to improve the health of its people by adding fluorine to its water supply. This is a question which has long since passed from the realm of scientific dispute, yet the matter is generally decided on the basis of letters to the editor and political expediency characterized by the most vociferous arguments being furnished by the most ignorant. The question of the abolition of capital punishment, the problem of juvenile delinquency, and the considerations related to controlling crime and rehabilitating criminals fall largely in the same category.

Birth of Legal Medicine

The birth of the modern concept of legal medicine seems to have occurred as a consequence of the Renaissance in Italy, and, as this new enlightenment spread to other countries of Western Europe, legal medicine became most deeply rooted in the Germanic countries. Starting in 1532, these nations took steps to establish a sound system of legal medicine and have been predominant in the field ever since. In 1650 Michaelis delivered the first lecture on legal medicine at the University of Leipzig, and as early as 1720 professorships in this science were founded by the state. At about the same time France also enacted laws which favored the growth of legal medicine, but in 1692 medicolegal offices became hereditary and the science languished until after the French Revolution.

During the 17th and 18th centuries the authority of Zacchias was supreme in this field, and it is interesting to take note of the principal problems with which he was concerned. He devoted chapters to such subjects as torture, sorcery, prophecy, and miracles. During this period doctors gravely discussed whether a woman could be got with child by the devil or by a dream and French judges legitimized an infant, when the husband had been separated four years from the mother, on the grounds that the child owed its paternity to a dream. It was generally taught that grossly deformed infants had a bestial parentage. The effect on a suspected murderer of touching the body of his supposed victim continued to be a legal expedient within the 19th century. Until 1726 cruentation was firmly established in medicolegal practice. It consisted in the belief that in the presence of the murderer the wounds of the corpse, no matter how long dead, would open and bleed afresh. Courts accepted the testimony of medical experts to this miraculous phenomenon.

Medicolegal autopsies were denounced until about 1750, and the work of Morgagni, the father of morbid anatomy, which is a foundation stone of legal medicine, was not published until 1761. So great was the helplessness of the science of legal medicine that a horrible atmosphere of suspicion encompassed the fear of death by poison. On those who were even suspected, the grossest legal abuses were everywhere inflicted, while those who were convicted were boiled alive by the English and burned by the French. The medicolegal authorities Paré, Zacchias, Hoffman, and others taught belief in ghosts, witches, and possession by the devil and united with the clergy in denouncing all disbelievers as heretics and atheists. The distinguished expert Hoffman condemned all those as witches who "vomited nails, hair, wax, glass or leather." Thus did the legal medicine of our ancestors only a few generations removed persecute, drown, and burn thousands of insane persons as "firebrands of hell" who are "moved and seduced by the instigation of the devil."

With the impotence of science to aid the law it adopted miracles as explanations, suspicion as proof, confession as guilt, and "torture as the chief witness"—the medical expert being summoned only to sustain the accused until the rack forced his confession.

Growth of Science and Legal Medicine

Just as the practice of medicine was an art long before it became a science, legal medicine began to contribute to the administration of justice only after the science of medicine began to develop. A hundred years ago most of the scientific measures now used in helping the law in the determination of the facts of a case were either undeveloped or totally unknown. Chemistry was in its infancy, as was pathology. Bacteria and viruses as a cause of disease were not even suspected, and the magic of the x-ray was undreamed of. The value of the microscope was not appreciated, and most of our everyday diagnostic equipment was still waiting for the inventor to uncover it. But, since there always seems to be a lag between scientific achievement and the adoption of its use in matters of law, legal medicine was years behind in the scientific parade.

In the United States the first chair of medical jurisprudence was established by the College of Physicians and Surgeons in New York in 1813. Two years later Harvard and the College of Physicians and Surgeons of the Western District of New York started instruction in legal medicine by professors of other branches. Since that time instruction in that branch in our medical schools has been spotty. Many give only token courses in this subject and some none whatever. In others the lectures consist of recitations by an old and grizzled coroner of interesting murder cases he was involved in decades before. In many schools the main object of the course seems to be to furnish entertainment rather than enlightenment. Not until 1937, when one was established at Harvard, did any medical school have a full-scale department of legal medicine. In the last two decades a few other schools have recognized the importance of the subject and followed the lead established in Boston. The failure of the medical schools themselves to appreciate the importance of the subject is one of the principal reasons that only at this late date is the importance of legal medicine beginning to be recognized.

Only a short time ago, when the American Medical Association was preparing a new medical directory, I was sent a card on which to supply certain information, including my specialty. There was no place on the card to indicate the subject of legal medicine. I therefore wrote saying that for several years I had devoted my full time to the practice of this specialty and would appreciate having the directory so indicate. By return mail I received a reply that the A. M. A. did not recognize that there was such a specialty, although for years THE JOURNAL has carried a column on that subject.

In 1815 Dr. T. R. Beck was appointed to give instruction in legal medicine at the Western New York School. He was the author of Beck's "Medical Jurisprudence," which first appeared in 1823. This book was so highly regarded and popular that for many years it was the classic on the subject and went through many editions, not only in this country but in Europe as well. The various subjects covered include feigned diseases, disqualifying diseases, impotence and sterility, doubtful sex, rape, pregnancy, delivery, infanticide, legitimacy, presumption of survivorship, age and identity, mental alienation, persons found dead, wounds on the living body, and poisons.

Psychiatry and the Law

Changes in the laws regarding insanity were initiated largely as a result of the problem of suicide in England. Under the old English law suicide was a felony, and the law required that a suicide be buried in the highway with a stake driven through the body and that his property be confiscated. Juries were more humane than the law and generally decided that suicides were insane and therefore irresponsible. Not until 1823 was this law rescinded, and the same year Beck congratulated the United States that "we do not war on the dead in this country."

In the United States, Maine took the lead in 1847 in enacting legislation to protect the insane person accused of crime. It provided that "any judge of the court before which he is to be tried, when a plea of insanity is made in court, or he is notified that it will be made, may order such person into the care of the superintendent of the insane hospital, to be detained and observed by him until the further order of the court, that the truth or falsity of the plea may be ascertained."

Until 1800 the test of sanity under Anglo-American criminal law was that he alone should be judged insane who was "totally deprived of his understanding and memory and did not know what he was doing any more than an infant, than a brute or wild beast." In 1812 it was decided that the correct test was whether the criminal had generally the power to distinguish right from wrong. Since 1843 in England and largely in the United States the test has been that at the moment the crime was committed the accused had a sufficient degree of reason to know that he was doing an act which was wrong.

Oddly enough, in spite of the tremendous advances made by psychiatry in the diagnosis and prognosis of mental illness, there has been no radical change in this yardstick of criminal responsibility.

In England in January, 1843, a man by the name of McNaghten was acquitted on a charge of murder on the grounds that he was insane. This verdict caused such a furor in the House of Lords that it resulted in a decision to have the 15 judges of the realm clarify the laws regarding criminal responsibility and mental illness. After considering the many angles of the problem, the judges propounded the rule that the test should be "whether the accused at the time of doing the act knew the difference between right and wrong." Kozol, in a masterly dissertation on this rule, states, "the authority of the McNaghten opinion appears to have done more to retard the advance of criminal justice in cases of homicide than all other factors combined." Nevertheless, that rule is still in force in virtually all states today.

Recently I was a witness at a trial for murder. The accused was a 23-year-old Negro boy who was charged with the murder of a police officer. He admitted that the police officer had suffered a nonfatal gunshot wound while he and the officer were struggling for a revolver. Seconds later another police officer in a car a short distance away started firing at the boy through the windshield of his car. Simultaneously the victim received a bullet through the head which, in all probability, was fired by the second police officer.

The court appointed a psychiatrist to examine the accused, and his report was most interesting. The boy had been born on a southern plantation and at a very early age the family had been abandoned by the father. The boy was sent to live with another family that had 13 children, and he had to sleep in a small room with six other persons. His mother moved to the West Coast, where, after a year or two, the boy joined her. She worked all day as a janitress, and he had little or no supervision.

This woman had a number of children by assorted fathers, most of whom were unknown. It is not surprising that he got into trouble at an early age. He had been in and out of numerous jails, prisons, boys' homes, and psychopathic hospitals. Psychological examinations revealed that he had an IQ of 54. He had not been involved in any vicious crimes but had been arrested many times for shoplifting, stealing bicycles, drunkenness, and comparatively minor offenses.

The psychiatrist's report revealed a most sordid story of impossible living conditions, neglect and abandonment of the boy by his parents, and inability to get a job because of his record or to hold one after he did find work. During the trial this boy repeatedly volunteered statements against his own interest, and his general conduct indicated to me that he had little concept of what he was facing. However, the psychiatrist's report ended with the usual statement that at the time of the alleged crime the accused knew the difference between right and wrong. It is not surprising that he was found guilty of first-degree murder.

Is it too deep in the field of wishful thinking to hope that before long society, with the aid of legal medicine, can prevent such occurrences as this double catastrophe—the death of the police officer and the mutilation of the life of this boy?

The first breakthrough of the ironclad McNaghten rules occurred in 1954 in the United States Court of Appeals for the District of Columbia. The accused was Monte Durham, who was charged with housebreaking, and he had a history remarkably similar to that of the boy just mentioned. In this case the court ruled "that the accused is not criminally responsible if the unlawful act was the product of mental disease or mental defect," and consequently the conviction of Durham was reversed.

This decision has received the enthusiastic approval of psychiatrists. Associate Justice Douglas of the Supreme Court noted with approval, "after the Durham case, as before, the jury has the final say. The jury evaluates the psychiatrist's testimony, as it does the evidence on every other factual issue. . . . No one theory of psychiatry is turned into a principle of law. [The psychiatrist] will be free to present his testimony about the mental condition of the accused in concepts that are familiar to him and medically realistic."

Future of Medical Jurisprudence

What of the future? A quizzical eyebrow might be raised as to why a paper on medical jurisprudence appears in a session on preventive medicine. The science of healing has taken thousands of years to pass through the various stages of recognition of disease, diagnosis, and treatment. The prevention of illness is the highest hope to which our profession can aspire. Legal medicine is now entering the stage where its special abilities can be employed to promote the administration of justice by preventing crime and accurately assessing criminal and civil responsibility. I shall offer just one illustration.

The polygraph is a scientific instrument based on sound psychological and physiological principles, and one of its major fields of usefulness lies in the prevention of theft and embezzlement.

Huge numbers of persons are employed in stores, banks, and other commercial institutions where they are constantly in contact with and handling merchandise and money which does not belong to them. We have not yet developed the concept that, to these employees, temptation to steal is an industrial hazard, just as electrocution is an industrial hazard to the lineman. When polygraph tests have been given to all of the employees of department stores, banks, and such institutions, the percentage who admit the theft of money or merchandise or shortchanging customers is astounding. In one series of tests involving all the employees of a group of 16 chain stores, 76% of the employees admitted one or more of the above derelictions.

None of these persons was discharged, but they were told that the test would be repeated in a year. On this occasion it was amazing to find that the percentage of derelict employees had dropped to 4. If all such employees were given a personnel examination which included a polygraph test as a preemployment measure, and if routine tests on all employees were conducted at regular intervals thereafter, I am convinced that theft and embezzlement would cease to be a problem. The money saved by the employer is, in my opinion, the least of the benefits derived. The real achievement is that the industrial hazard of temptation has been canceled and a previously honest person has been saved from becoming a thief.

All of the multiplicity of branches of scientific medicine are advancing at a headlong rate. New drugs are appearing in such profusion that before we learn how to spell the names of them they have become obsolete and others with unpronounceable names have taken their place. Diagnostic and surgical procedures which are commonplace events were undreamed of only 10 years ago. Slowly but surely the laws are being molded to make use of this vast expanse of scientific knowledge in the administration of justice. As people generally become aware of these advances the laws ultimately have to conform to encompass and use new and more reliable information. Laws never create public opinion, but laws sooner or later always have to conform to public opinion, just as the McNaghten rules are giving way to the enlightened concepts of psychiatry.

Comment

In traveling about the country one cannot fail to notice that all of the older courthouses have one thing in common—a symbolic statue of Justice. It may be over the front entrance or on the cupola, but invariably it is present. Justice is depicted as a

Roman goddess with long, flowing draperies. She is blindfolded. Held aloft in one hand is a pair of scales which generally are somewhat tilted, and in the other hand is grasped the two-edged sword of retribution.

With the enlightenment of modern science and the helpfulness that legal medicine now has available, is it not time to revise this concept of Justice? I would suggest that in place of the Roman goddess we substitute a trim, intelligent young woman wearing a laboratory coat. I would remove the blindfold. Is there any reason why Justice should not see and observe as well as listen? Is not a witness giving testimony before a jury judged as much by his appearance, his manner of speaking, and the shrug of the shoulder as by what he says?

In place of the old scales let us substitute a modern analytical balance which can weigh the tiniest grain of sand with complete accuracy, and in place of the two-edged sword of retribution let us recognize that science now offers a humane, intelligent approach to rehabilitation.

Science has provided the tools; it is up to society to see that the law uses them: "For what is so important as the administration of justice?"

CLINICAL TRANSFORMATIONS IN PSYCHIATRY AND PSYCHOANALYSIS

Gregory Zilboorg,† M.D., New York

Psychoanalysis was originally distinct and isolated from clinical psychiatry. European psychoanalysts rarely had university connections, were little interested in custodial intramural psychiatry, and preferred to deal with neurotic rather than psychotic patients. In the United States there has been a synthesis of clinical psychiatry with psychoanalysis, and the latter is well represented in university medical schools. The synthesis was accelerated by World War II, and there is a trend toward establishing the biopsychological unity of the human person. The future of this synthesis remains unclear, however, and the responsibility for establishing the scientific status of psychoanalysis will rest on the shoulders of the clinical workers in this country.

A proper appraisal of the reciprocal influences between psychoanalysis and psychiatry is not yet possible; only the general trends of a possible historical perspective will be outlined here. For today, 103 years after Freud's birth and about 20 years after his death, the true medicopsychological role of psychoanalysis still appears uncertain. World War II must have played a serious role in making so many things uncertain, and many things scientific and medical have fallen victim to the widespread uncertainty.

Psychoanalysis and Clinical Psychiatry

In the 20's of this century psychoanalysis, while at one of its heights of development, still remained more or less isolated from clinical psychiatry. The centers of psychoanalysis and psychoanalytic education were in Vienna and Berlin. The medical profession as a whole was academically and scientifically removed from the psychoanalytic clinicians and theoreticians. However, there were a few isolated persons whose contact with clinical psychiatry was close, at least intermittently, although their main preoccupation was with psychoanalysis. Among these the names of Abraham, Wittels, Simmel, and Nunberg ought to be mentioned. Abraham was trained in Burghölzli under Eugen Bleuler; Simmel was interested in the intramural psychoanalytic treatment of patients who were nearly psychotic. However, psychoanalysis as a whole was not interested in clinical psychiatry; its chosen and self-limited field was that of *neurosis. Psychoses could* perhaps be "understood" psychologically, but the field of psychosis was considered as belonging to custodial intramural psychiatry. Psychiatry was considered "academic"—old, static, and generally unproductive—despite the contributions of Eugen Bleuler, who definitely acknowledged his debt to psychoanalysis, or later those of Schilder and Ernst Kretschmer.

Reference has been made here almost exclusively to German-speaking sources. In England psychoanalysis was still in its early stages of development and, as if following the German tradition, it at first stood quite apart from clinical psychiatry. (One must add that clinical psychiatry invariably responded in kind and in isolationist fervor.) As to France, the wounds of World War I delayed the spreading of psychoanalysis into that country until almost the end of the 20's—and the delay was also

---

Read before the Section on Nervous and Mental Diseases at the 108th Annual Meeting of the American Medical Association, Atlantic City, June 10, 1959.

†Dr. Zilboorg died Sept. 17, 1959.

on the basis of mutual and reciprocal scientific isolationism, as far as the psychiatric traditions were concerned.

The picture in the United States presented almost entirely different aspects. The first to try out, or tentatively to test, the new ideas of psychoanalysis were such seasoned and well-schooled psychiatrists as Charles Macfie Campbell and August Hoch, in the early days of the century, in what was then known as Bloomingdale Hospital, now the Westchester Division of the New York Hospital. A little later John T. McCurdy presented the first attempt in this country to lay the groundwork of "dynamic psychology." One of the assistants of the neurologist Frederick Peterson became the well-known pioneer of psychoanalysis in America, A. A. Brill. Among the founders and charter members of the first psychoanalytic society in America one finds the names of Adolf Meyer, Louis Casamajor, Smith Ely Jelliffe, and William A. White.

In other words, in America psychoanalysis was introduced primarily by clinical psychiatrists, by physicians whose experience was in intramural and extramural psychiatry and in research laboratories, by nonpartisans of the psychoanalytic movement. Theirs was a purely scientific, clinical interest. Consequently psychoanalysts in America, at the beginning, were more interested in psychosis than were their European colleagues.

It is rather curious, if not entirely paradoxical, that Freud, who fought such a valiant battle before the Viennese Medical Society because the latter would not recognize that hysteria can exist in men (a battle that had seemed to have been settled in favor of Freud since the days of Sydenham, if not earlier), and who was the champion of the psychoanalytic treatment of hysteria as the preferred treatment, had to discover soon that there actually were not enough hysterias to go around. Today, as we move deeply into the third quarter of the 20th century, hysteria as an actual clinical entity has become a matter of the past; the clinical pictures which were so well depicted by Charcot and by Pierre Janet seem to have gone into history, even as did typhoid in the large cities of the United States, or malaria before World War II. The reasons for the disappearance of so-called pure hysteria and even of anxiety hysteria, which Freud very early wished to establish as a separate clinical entity, remain a mystery.

There is a possibility, of course, that many conditions which were in the past diagnosed as hysterias, or even hypochondrias or neurasthenias, can be found today in that indefinite mass of hyphenated clinical entities which bears the name of psychosomatic conditions. Yet it is not easy even to venture a guess as to why a whole "class" of mental conditions suddenly almost disappeared from the field of our clinical purview. The "universal" neurosis of today has become the compulsion neurosis, or the so-called borderline case.

Toward a Medicopsychological Synthesis

Among the contributions which psychoanalysis has made to psychiatry there is one—albeit a possibly negative one—which must be mentioned: Psychoanalysis seems to have almost effaced the lines of demarcation which had existed between the various clinical entities theretofore known as Kraepelinian nosology. Psychoanalysis, whether the prewar European type or the American, stressed the psychological understanding of the patient rather than a consideration of the patient's clinical, nosological aspects. While this contribution cannot be overestimated, one may not overlook the negative influence it has had on psychiatric nosology.

It should be borne in mind that Freud never was a well-schooled psychiatrist. The little he learned from Meynert served small purpose in the course of Freud's fascination with his own early discoveries. Nor did Freud appear to learn much from Kraepelin, who was, after all, his contemporary. Kraepelin was the last serious representative of the Hippocratic tradition in psychiatry, almost the last in the line of great neurologists and psychiatrists whose scientific origin could be traced from Sydenham, Haslam, Pinel, Esquirol, Morel, and Magnan, and perhaps Charcot. Freud started with the latter, but his was not the path of objective, external, clinical description; his was the search for objective considerations of the subjective states of his patients. Freud, from around the year 1896, started to drift away from the purely externally objective and physicopathological, while Kraepelin completed in the same year his monumental nosological differentiation of the major psychoses. Thus the conflict between psychoanalytic (Freud) and academic (Kraepelinian) psychiatry can be considered not so much a conflict as a bifurcation of the main current of psychiatry into two branches, both flowing from the same main river but neither, despite its apparently independent strength, able to continue its independent existence for long. A synthesis, a clinical and scientific convergence, had to take place some day.

In our own time many factors have interfered with the possibility of such an early synthesis. First of all was the factor of Freud's own personality. His genius tolerated little opposition. More often than not he treated such opposition as personal affront; his relationships with Breuer and later with Wagner-Jauregg could be cited as typical. Then, too, psychoanalysis became a movement. Having early been ostracized by the academic circles of psychiatry, psychoanalysis seemed to turn toward academic isolationism; in a way, it excluded itself from the universities and schools of medicine. Freud even began to insist that psychoanalysis was a science *sui generis*, independent of medicine, a sort of supramedical or extramedical specialty, yet rooted deeply in psychopathology.

This trend continued with variable strength until the mid-30's. Psychoanalysis acquired more numerous adherents, while academic psychiatry began slowly to utilize the major Freudian concepts in order to gain a better psychological understanding of psychiatric patients. It was but natural that psychiatry as a whole, as far as psychoanalysis was concerned, should remain eclectic. It followed on the whole the path which had been marked by Eugen Bleuler, the first efficient and scholarly academic psychiatrist to utilize many of the conceptual constructions which psychoanalysis had to offer. Freud was not satisfied with Bleuler's cautious clinical attitude toward psychoanalysis. While Freud, with his characteristic cold but telling irony, suggested that no one but Bleuler could have invented the term ambivalence because of his own ambivalence toward psychoanalysis, it remains historically clear that Freud's fascination with Fliess's theory of polarities in human psychology, and his own dialectics, led to the concept of ambivalence—which Bleuler was keen enough to grasp and introduce into common usage in psychopathology.

Influence of World War II

The events which led to the advent of Hitler and to World War II had a truly revolutionary effect on the outer and inner relationships between psychiatry and psychoanalysis. The skeptical traditionalist in medicine, who shies away from the intimate coupling of sociological and political events with profound changes in the practice of any branch of medicine, should bear this in mind. It is true that certain ideological movements in the past changed little the course of medical development. The French Revolution, for instance, neither created nor prevented from appearing such hospital and nosological reformers as Philippe Pinel and Esquirol. On the other hand, the Communist revolution eradicated the teaching and practice of any psychopathology unless it were based on the reflexology of Bechterev and later on that of Pavlov (until today, in international congresses and in personal encounters, Russian psychiatrists deem it necessary to offer physiological reflexology or nothing).

But the Hitlerian catastrophe produced an even greater revolution in clinical psychopathology than the French Revolution, which established the primacy of the middle class, had in the field of economic change. Hitler not only burned the books of Freud and forced the old Freud out of Austria to England, where he died; the leading minds in the field of psychoanalysis emigrated from Germany, Austria, and later on from France to the United States. The ranks of psychoanalysis in America were immeasurably reinforced, as far as prestige and scientific productivity were concerned.

And it soon became clear that psychoanalysis in America, in order to sustain itself scientifically as well as economically, had to become truly a branch of medicine, a medical specialty. Moreover, the academic freedom and elasticity of the scientific atmosphere of America opened to psychoanalysis doors which had seemed to be thoroughly closed to Freud and his earliest followers in Austria and Germany; I have in mind the field of university instruction. Franz Alexander became the first professor of psychoanalysis in the world (at the University of Chicago). Hanns Sachs began to teach in the department of psychology at Harvard.

Soon the "younger generation," the first American students of the scientific émigrés, began to gather into groups of personal followers. Official psychoanalysis remained a movement; as it strove to maintain its independence, it also began to show signs of division, of trying to become a part of American academic life yet independent of it, of remaining a part of the central psychoanalytic organization yet independent of that as well. Some failed, some succeeded, in carrying out this rather delicate self-imposed task. Thus Karen Horney was led to create her own school, which became more sociological and philosophical than psychoanalytic, while Sandor Rado became the head of a psychoanalytic school which became a part of the College of Physicians and Surgeons of Columbia University.

Greater and greater numbers of properly trained younger Americans entered the field of psychoanalysis. Only 14 years after the conclusion of World War II, one can easily find more than a dozen psychoanalysts who are members of the departments of psychiatry throughout the United States. In other words, not only has psychoanalysis ceased to be an impediment to a medical academic career but at times it seems to have become an advantage.

The war years brought about significant developments. The concept of the dynamic unconscious, of the therapeutic value of bringing into consciousness that which is buried in the unconscious, was the underlying principle which led Roy Grinker to his experimentation in the North African campaign which for a while bore the appellation of narcoanalysis. The combined utilization of drugs or insulin and electric shock therapy, which—it is generally claimed—makes patients more amenable to psychotherapy, are all signs of our psychoanalytic times. Whether it is officially recognized or not, the chief conceptual trends of psychoanalysis, even in their eclectic form, have become incorporated as an inseparable part of our clinical psychopathology and therapeutic work in psychiatry.

Yet it would be a mistake to believe that the process of incorporation of psychoanalysis into psychiatry preserved the conceptual structure of psychoanalysis in its integrity. It is rather regrettable to note that while official or orthodox psychoanalysis is now more wedded to the main source of clinical psychopathology, i. e., psychiatry, it has drifted more into the field of theoretical elaborations, rather than the clinical and tangible which characterized the most brilliant work of Freud during the first half of his career. At the same time, one must acknowledge that this aspect of the postwar phase of psychoanalysis may be but a passing phenomenon. It is difficult to fathom the final outcome, but this much can be said: The responsibility for the scientific future of psychoanalysis must rest on the shoulders of the clinical workers of the United States. The extent of the devastation of Europe in this respect may be judged from the fact that the *International Journal of Psychoanalysis*, published in England, contains more contributions by workers from the United States than from other countries. The same can be said to be true, but to a much greater extent, of the scant, impoverished psychoanalytic publications in Germany.

Psychosomatic Medicine

A word or two about the most conspicuous and dramatic postwar development—I have in mind the field of psychosomatic medicine. From the standpoint of historical perspective, the development of psychosomatic medicine was not necessarily a result of World War II. Rather, it was a result of the spontaneous impulse toward a synthesis between psychopathology and general medicine. It was general medicine that still preserved a sort of unity of the Hippocratic tradition; it dealt with disease entities, yet it began to feel the need of considering the biological unity of the human person. On the other hand, psychiatry—whether it was frozen in depersonalized classifications and preestablished prognoses, or wedded to eclectic psychoanalysis and therefore of necessity more speculative—began to feel the need of preserving the psychological unity of man.

It is this, I believe, that explains the trend of establishing the biopsychological unity of the human person. It was out of the same psychological and scientific needs that the original "psychosomatic" medicine was born in Germany in 1838 (see my "History of Medical Psychology"); it was as a result of the same necessities that psychosomatic medicine reappeared exactly 100 years later in the United States (the first work of Flanders Dunbar was published in 1938). Thus the emotional, unconscious matrix of many of our physical symptoms received scientific recognition. This would have been impossible without Freud's theories of the dynamics of the unconscious and his concept of conversion and of displacement of emotional charges. The enormous amount of research done in this field cannot be overestimated. Some psychoanalysts, like Alexander, have turned almost exclusively to psychosomatic research; others, like Felix Deutsch, have made substantial contributions to this field. Whether psychosomatic medicine is here to stay as a specialty, or a subspecialty, is doubtful. For, after all, the field of internal medicine, enlightened as it has become by psychopathology (particularly psychoanalytic psychopathology), cannot remain both a medical and a psychiatric specialty. Problems of medical instruction and clinical differentiation arise which only the future can solve. Born out of historical necessity, psychosomatic medicine remains overburdened with new problems which medicine seems to be unable to solve and which psychiatry is as yet able merely to give names.

Thus, it seems justified to say that while World War II accelerated to an enormous extent the synthesis of psychoanalysis, psychiatry, and medicine, this synthesis seems now in the midst of a turbulent and confusing phase. The future of this synthesis is as yet neither clear nor otherwise determined.

33 E. 70th St. (21).

COUNCIL ON DRUGS

NEW AND NONOFFICIAL DRUGS

The following descriptions of drugs are based upon available evidence and do not in any case imply endorsement by the Council.

H. D. Kautz, M.D., *Secretary*.

Amphotericin B (Fungizone).—An antibiotic substance derived from strains of Streptomyces nodosus. The commercial preparation represents an amphotericin B-sodium desoxycholate complex.

Actions and Uses.—Amphotericin B is an antibiotic agent which is used for the treatment of deep-seated mycotic infections. Its spectrum of activity against the yeast-like fungi, both in vitro and in vivo, appears to be wider than that of any other antifungal agent now available. Thus, included among the fungi against which amphotericin B is active are Coccidioides immitis, Histoplasma capsulatum, Cryptococcus neoformans, Blastomyces dermatitidis, Blastomyces brasiliensis, and species of Candida. It has no demonstrable effect on viruses, protozoa, or bacteria. Against susceptible yeasts and fungi, the drug is fungistatic rather than fungicidal. Amphotericin B is relatively insoluble in water and is poorly absorbed from the gastrointestinal tract. Hence, it should be given parenterally, despite a few reported instances in which deep mycoses responded to orally administered amphotericin B. The drug is very slowly excreted by the kidneys; demonstrable blood levels persist for 18 hours or more after the intravenous injection of a single dose. To date, there is no clinical evidence of acquired resistance by previously susceptible micro-organisms to the antifungal action.

of amphotericin B. However, resistance of Coccidioides immitis and some species of Candida can be developed in vitro. In the case of the Candida organisms, this is sometimes associated with cross resistance to nystatin.

Amphotericin B is effective against some mycotic infections which have been notoriously refractory to all previous modes of therapy. The most gratifying results have been obtained in patients with disseminated North American blastomycosis. In many cases, arrests and apparent cures of serious and widespread infections have been reported. Since it is more effective than stilbamidine or hydroxystilbamidine, amphotericin B will, no doubt, supplant the diamidine bases as the drug of choice for the treatment of serious pulmonary and systemic North American blastomycosis. Limited clinical data suggest that it may be equally effective in the South American variety of the disease.

Excellent results have followed the use of amphotericin B in many, but not all, patients with severe, disseminated histoplasmosis. This is in contrast to the uniformly disappointing results with other agents previously tried for the chemotherapy of this disease. Although detailed and prolonged follow-up studies will be necessary to determine its exact therapeutic value, the many arrests and apparent cures already reported indicate that amphotericin B is the drug of choice in disseminated histoplasmosis. The drug has been observed to cause sputum conversion in patients with chronic cavitary pulmonary histoplasmosis and may also prove useful in the recently described entity of mediastinal histoplasmosis.

The results of therapy in meningeal cryptococcosis (torulosis) have been less favorable than in blastomycosis or histoplasmosis. There have undoubtedly been some complete therapeutic failures. Nevertheless, amphotericin B has been shown to have a definite chemotherapeutic effect in numerous patients with this disease. To date, the most encouraging results have been obtained in patients with subacute cryptococcosis. Despite the inability to consistently detect appreciable concentrations of amphotericin B in the spinal fluid, some patients with cryptococcic meningitis have experienced remissions of clinical symptoms, with a reversal of positive spinal fluid cultures after intravenous administration of the drug. It is too early to determine whether these cases represent cures. The drug has also been used intrathecally, with favorable results in some patients who did not respond to intravenous therapy. Although therapy with amphotericin B is not always effective, cryptococcic meningitis has responded favorably more often with this drug than with any previous agent. Currently, it should be the drug of first choice for this disease. In disseminated cryptococcosis without meningeal involvement, results have been better than in the meningeal form of the disease and are about equivalent to those obtained in blastomycosis and histoplasmosis.

Amphotericin B appears to be of some usefulness in the treament of disseminated coccidioidomycosis. However, results have been quite variable. Some patients show no response whatever to the drug. Others, including a few with coccidioidal osteomyelitis, have been markedly benefited, with apparent arrest of the disease. It is still too early to determine whether coccidioidomycosis has actually been cured by amphotericin B. In view of the poor prognosis of disseminated coccidioidomycosis and the inadequacy of all other forms of therapy, a therapeutic trial of amphotericin B is indicated. The drug does represent a definite advance in the management of this disease. There is evidence that amphotericin B given intravenously along with intrathecal therapy sometimes produces a better therapeutic response in patients with coccidioidal meningitis.

There is some evidence that generalized systemic moniliasis (candidiasis) may be favorably influenced by the use of amphotericin B. At the present time, however, clinical experience has been too limited to permit conclusions as to the ultimate effectiveness of the drug. Likewise, its relative usefulness against one species of Candida versus another is uncertain. Despite these inadequacies, however, it already seems apparent that amphotericin B is far more useful in systemic moniliasis than is nystatin. Although there is still good reason to seek better drugs, amphotericin B appears to be the most promising agent currently available for the treatment of this condition.

Toxicity and Side-effects.—The full spectrum of toxic manifestations to intravenously administered amphotericin B may not yet be characterized. Clinical experience indicates, however, that unpleasant and sometimes potentially dangerous side-reactions are almost inevitable at therapeutic dosage levels. Hence, amphotericin B should be used only in hospitals in which close clinical supervision of the patient is possible.

Systemic reactions, consisting of anorexia, headache, chills, and fever, are frequently encountered during the first few days of amphotericin B therapy. These tend to subside with continued administration and may be minimized by the concomitant use of antipyretics and/or antihistaminics. If a severe reaction occurs during the course of an infusion, therapy should be interrupted for about 15 minutes and then reinstituted. If the reaction recurs, therapy should be resumed at a lower dosage the next day.

The majority of patients show a rising level of blood urea nitrogen after prolonged therapy with the higher doses of amphotericin B. This toxic effect, together with other chemical evidence of renal dysfunction, is the chief limiting factor in the dosages which may be employed. Fortunately, to date, renal function has regularly returned to pretreatment levels after discontinuance of amphotericin B therapy. It follows, therefore, that blood urea nitrogen and nonprotein nitrogen levels should be checked routinely during therapy with amphotericin B. If the blood urea nitrogen or nonprotein nitrogen levels exceed 20 mg. per 100 ml. and 40 mg. per 100 ml., respectively, administration of amphotericin B should, in most cases, be stopped until these levels return to normal limits (usually one to two weeks). In some cases in which the clinical condition of the patient has warranted it, these values have been far exceeded, with no apparent evidence of permanent renal impairment. Kidney function tests should be done at appropriate intervals during prolonged therapy.

Solutions of amphotericin B have an irritating effect on the venous endothelium. Thus, pain at the site of infusion and chemical thrombophlebitis may follow its use. Thrombophlebitis may be minimized by decreasing the concentration of the infusion solution below 0.1 mg. per cubic centimeter, reducing the rate of infusion, frequent shift in sites of venipuncture, and using a smaller gauge needle. Among the miscellaneous side-effects to the drug are occasional instances of anemia during prolonged therapy and gastrointestinal cramping and diarrhea; a few patients have also developed a maculopapular drug rash.

In view of its appreciable toxicity, amphotericin B should be given only to patients in whom a diagnosis of susceptible mycotic infection has been reasonably substantiated, preferably by positive culture. There is not adequate justification for its use in vague and undiagnosed conditions merely because a skin test for one of the fungi may be positive. Once therapy has been initiated, quick cures should not be expected; prolonged therapy for a number of weeks or months may be necessary. The tendency to increase the dosage to the highest level recommended, or even higher, in the hope of obtaining a more prompt remission or cure should be discouraged. It is preferable to adjust the dosage to obviate renal damage and to prolong the time of treatment rather than to use higher dosages which are inherently accompanied by greater toxicity. The dosage may be so adjusted either by keeping below the maximal recommended daily dosage or, preferably, by administering the maximal daily dosage every other day.

Dosage.—Although amphotericin B has been tried on an experimental basis by the oral route, by topical application, and by various other parenteral routes (intra-articular, intrapleural, intralesional, intramuscular), the drug is presently considered suitable for use only by slow intravenous infusion and, in coccidioidal meningitis, by intrathecal injection. For intravenous infusion, unless venous irritation or thrombophlebitis necessitates using a more dilute solution, concentrations of 0.1 mg. per cubic centimeter are generally employed. Such solutions are prepared from the sterile lyophilized powder by appropriate dilution with 5% dextrose in water for injection. Saline solution should not be used since it will cause the amphotericin B to precipitate. The rate of administration should be adjusted so that the total dose is infused over a three-to-six-hour period. For intrathecal injection, the dosage should be gradually increased up to a maximum of 0.7 mg. The drug is diluted with sterile water for injection to a final concentration of 0.25 mg. per cubic centimeter and then admixed in the syringe with spinal fluid. Intrathecal injections should be repeated every 24 to 48 hours.

Since tolerance to amphotericin B varies among individuals, dosage must be adjusted according to the specific response of each patient. Therapy is initiated with a daily dose of approximately 0.25 mg. per kilogram of body weight. This dose is gradually increased until an optimum level is attained. Generally, total daily dosage may range up to 1.0 mg. per kilogram. Within this range, dosage should be maintained at the highest level not accompanied by toxic manifestations. In seriously ill patients, who do not respond to doses of 1.0 mg. per kilogram of body weight, this dose may be exceeded cautiously and gradually up to a maximum of 1.5 mg. per kilogram, provided no significant toxic effects are encountered. Since amphotericin B is excreted very slowly, if necessary, therapy may be given on alternate days to patients on the higher dosage schedule. Under no circumstances should the total daily dosage exceed 1.5 mg. per kilogram of body weight. Whenever medication is interrupted for a period longer than seven days, therapy is resumed by starting with the lowest dosage level, i. e., 0.25 mg. per kilogram, and increased gradually to an optimum level as outlined previously.

When substantial improvement is observed, daily administration of amphotericin B may be substituted for therapy on alternate days. Duration of therapy is variable. In clinical experience to date, significant improvement has been observed in most instances within four to eight weeks of treatment at full therapeutic dosage. A shorter period of therapy appears to produce a less favorable response and may lead to relapse.

Amphotericin B is heat labile and light sensitive. Hence, both the dry powder and solutions of the drug should be stored in the refrigerator and protected against exposure to light. Unused solutions should be discarded after 24 hours.

Preparations.—powder (injection) 50 mg.

Year of introduction: 1958.

E. R. Squibb & Sons, Division of Olin Mathieson Chemical Corporation, cooperated by furnishing scientific data to aid in the evaluation of amphotericin B.

From water emergencies to medical crises at home, fire department rescue squads are ready for immediate help, before doctor arrives.

Directory of Dedication

A 104-page directory published without fanfare last month provides the first documentary evidence that the A. M. A.'s broad activities for the well-being of the nation's population sprout from a tree measuring a figurative 1,100 people high.

These persons, many of whom serve in week-end and late night sessions, donate as many as 100 hours yearly to the Association. None of the 1,100 is on the A. M. A. payroll. The volunteering M.D.'s (and Ph.D.'s and LL.D.'s and B.A.'s too) range in name from A (Adams, Wright R.) to Z (Zopf, L. C.) and come from all 50 states. Their talents enrich 13 A. M. A. Councils, more than 100 Committees, 21 Sections of the Scientific Assembly, 10 specialty journals, and approximately a dozen liaison groups.

But whether the dedicated doctor serves in a scientific role on a Standard Nomenclature or Residency Review Committee or contributes socioeconomic know-how as a key legislative man—or is an A. M. A. officer or Board of Trustees member who attempts to interweave the profession's far-reaching roles—his efforts eventually find focus in the 210-member House of Delegates. For this ultimate volunteer parliament sets Association policy.

Last month's directory lists approximately one-fourth of the 1,100 persons who form the heart of the Association's "advice and decision." (There will be no broad distribution of the volume.)

Rescue Squads Get There First In Providence Emergencies

One of Capt. Fred Badger's prized mementos is a Father's Day card from a child not his own. Captain Badger commands a fire department rescue squad in Providence, R. I., and the card is from a child he helped deliver five years ago on the city's traffic-crowded streets.

It is only one of hundreds of expressions of appreciation that members of the city's rescue squads have received from those they have helped in 17 years of emergency service. The squads deal in the unexpected and the critical. The men are trained in such diverse arts as emergency obstetrics and the use of a metal-cutting torch. Their list of equipment ranges from hypodermic syringes to diving suits.

The first squad was formed in 1942 in the face of skepticism, both lay and medical. Today the service is answering an average of 550 calls per month, and two of its proudest possessions are plaques awarded to it by the Providence Medical Association for outstanding service to the community.

Providence's first rescue squad resulted from an attempt by the city's public safety departments to find a better way to provide quick relief in emergencies, many of them medical. Men of the fire department were carefully screened and trained for the work before the first unit was activated. "This was an entirely new service with which the public was not at all acquainted," says Fire Chief Lewis Marshall. "Public confidence had to be gained, and the only way to get it was by rendering outstanding service."

Public confidence was gained, and at a rate that necessitated the addition of a second squad in 1952 and a third in 1957. Chief Marshall says, "Although the number of calls this year is running slightly ahead of last year, it appears that the saturation point has been reached."

The faith of Providence physicians in the service is indicated by the fact that more than a third of its calls come either from doctors themselves or from the Providence Medical Exchange. Dr. William J. O'Connell, former president of the Providence Medical Association, awarded the squads their plaques for outstanding service in 1955. He said, "There are few among us who have not had occasion to work with one of these units, to know how capably they are trained for their tasks, and how unselfishly they serve."

The only thing typical about a rescue squad call is its emergency nature: It may be a child struck by a speeding car, a worker caught in a large transmission belt, a woman in imminent labor, or an elderly man slumped at his desk. The rescue vehicle answering the call goes equipped with a physician's bag—a gift of the Providence Medical Association—and the doctor can be confident that high-quality first-aid procedures will keep the victim as safe and comfortable as possible until he arrives.

Dean of the Providence rescue firemen is the 63-year-old captain, Fred Badger, whose "10 or 15" injuries in the line of duty attest to the rugged tasks the squads perform. But when things are quiet he has a less demanding avocation—weaving soft-as-down crib blankets on a home-made loom.

Poison Control Centers Are Medicine's Stitch in Time

When baby eats the aspirin, tastes the laundry bleach, or plays with the ant powder, it is usually the family pediatrician who receives a hurried call from a distraught mother.

Small wonder, then, that the meeting of the American Association of Poison Control Centers was held in Chicago this week during the annual meeting of the American Academy of Pediatrics. It was the academy's awareness of the magnitude of the problem of accidental poisoning that was in large measure responsible for the birth in Chicago of the first of the 270 poison control centers now operating in the United States. (See Medicine at Work, The Journal, Jan. 12, 1957.)

It was in 1953 that the Illinois chapter of the academy sparked the formation of a poison control committee. Members included representatives of the American Medical Association, the Food and Drug Administration, the National Safety Council, and the five Chicago medical schools. The success of the committee's pilot study, which used the facilities of six Chicago hospitals and the Board of Health, stimulated similar efforts in cities throughout the nation.

Operated chiefly by hospitals and departments of health, these centers are aided in their task of making accurate information available by such units as the A. M. A. Committee on Toxicology and the National Clearinghouse for Poison Control Centers, operated by the Public Health Service.

As the association met, still another effort at awakening the American people to the dangers of accidental poisoning was under way. In Congress the House Judiciary Committee had reported favorably on a resolution requesting President Eisenhower to designate the second week in October as National Poison Prevention Week.

Chat with a Soviet Medical Leader

Q—Do nonphysicians set medical research goals in the Soviet Union? A—No. Doctors of the academy of sciences do that.

Q—What are some significant drugs in process in your country? A—A new antibiotic for the treatment of cancer and some improved anticoagulants. We also have a different treatment for hypertension which includes a regimen of four or five small meals a day for the patient.

Q—What is the status of mental illness generally and alcoholism specifically in Russia? A—Mental illness is down. Alcoholism is not much of a social problem in the U. S. S. R. and is not a medical problem at all.

Q—What proportion of physicians in the Soviet Union are members of the Communist Party? A—It is difficult to say. Certainly less than half.

The questioners are newsmen at the Second World Conference on Medical Education. Doing the answering is Dr. Zigmas I. Yanushkevichius, aged 48, born in Soviet Georgia, director of the Kaunas Medical Institute in Lithuania, specialist in cardiology and a leader in Russian medical education, holder of two Orders of the Soviet Union. At the news conference Dr. Yanushkevichius made these additional points:

—Like Americans and people elsewhere, Russians get tense and nervous—overworking, running for busses and subway trains, under-resting and overeating. The population is showing a rise in the incidence of heart disease and high blood pressure.

—"I cannot evaluate the comparative status of Russian and U. S. medical research. Am I not a guest in this country?"

—While every medical school graduate must practice in one of the districts for at least three years at a starting salary equivalent to $187 a month, incentive pay of up to four times that amount is offered for service in remote regions of the nation. Medical school professors get as much as $1,250 monthly.

—The Soviet Union is catching up in its need for engineers. As a result more men are studying medicine in Russia, where 70% of the physicians now are women. Some 200,000 students are being taught by 19,600 professors in 87 Russian medical schools. Eighty per cent of the students live in dormitories.

Most of the replies were given in English, although an interpreter was present for the occasional clarification of a question or answer.

Medical Education: Key to Health

Its Vital Role Is Emphasized by Physicians at a World Conference

> Every country has something unique to offer from its experience in medical education. No two schools of medicine, or their programs, are exactly alike. There is much to be learned from different experiences, and this second world conference can only advance the welfare of mankind in ways which are above political differences, race, and creed. Doctors and educators meet on the common ground of the welfare of the individual human being wherever he lives.

The speaker, an American, is a leading educator as well as physician. And as Dr. Raymond B. Allen, chancellor of the University of California at Los Angeles, thus opens the Second World Conference on Medical Education, he sees in his Chicago audience men of medical education who are of different politics, races, and creeds. They include:

Dr. Zigmas Yanushkevichius of Soviet Lithuania.

Dr. Romeo Y. Atienza of Manila.

Dr. Abdel Mohsen Soliman of Cairo.

This conference, continuing an effort first begun in London in 1953, brought together from 61 different countries more than 1,500 persons concerned with medical education. Special booths were set up in the assembly hall for interpreters to make simultaneous translations in English, French, and Spanish. Besides these formal presentations, which were keyed to the theme, "Medicine—A Lifelong Study," there were 125 scientific papers on topics ranging from medical student preceptorship to advanced research, a series of exhibits on electronic advances in medical science, visits to Chicago-area medical centers, and closed-circuit telecasts of medical roentgenographic images from nearby Cook County Hospital to the downtown convention hotel.

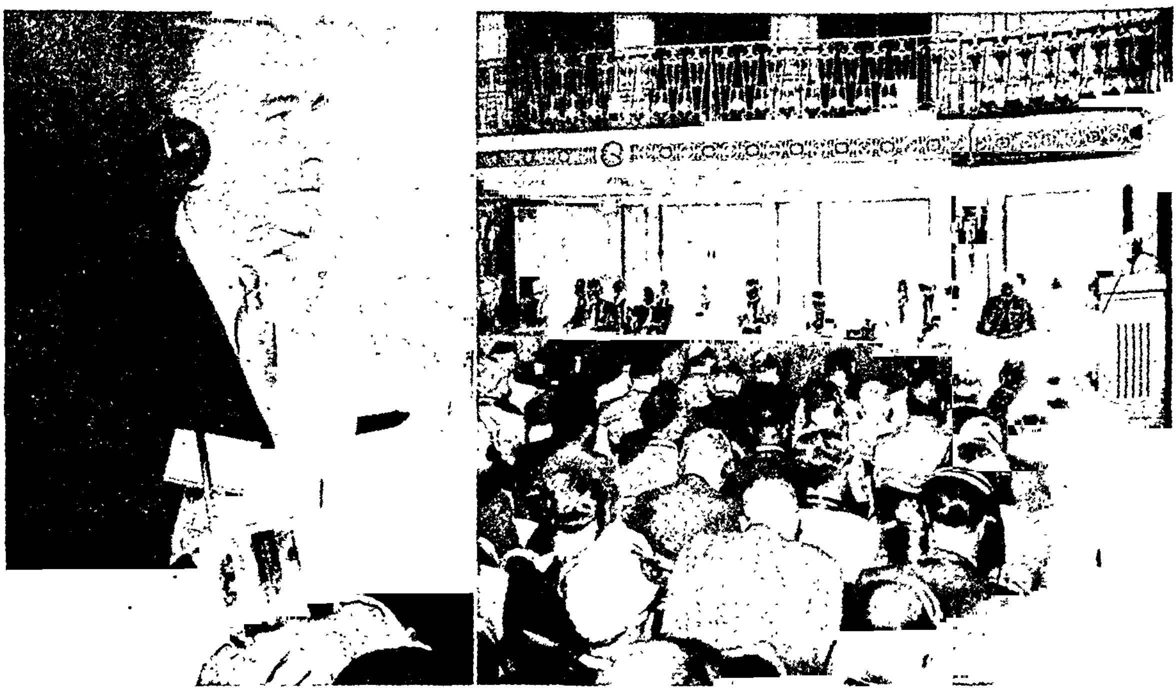
As illustrative of the broad fields covered by participants, the conference was sponsored jointly by four wide-ranging organizations: the World Medical Association, the World Health Organization, the Council for International Organizations of Medical Sciences, and the International Association of Universities.

Excerpted highlights from selected papers, delivered at the conference Aug. 29 through Sept. 4, follow:

On the meeting itself—

> There is an urgent need, throughout the world, for more well-trained physicians, nurses and other health workers. Only through such personnel can the benefits of modern science be brought to bear on mankind's eternal struggle against disease, suffering, and death. At your conference experts from many nations exchange knowledge and ideas in this life-giving field. Their work advances the cause of medical education and strengthens the bonds which unite the family of man.
>
> —Letter from President Eisenhower read by Dr. Allen.

> This week-long meeting provides a common ground for the free exchange of scientific informa-



Scenes from Second World Conference on Medical Education, in Chicago. A. M. A. President Louis M. Orr, at left, listens to portable receiver which can be dialed for simultaneous translations in English, Spanish, or French. At right, audience hears remarks of Dr. Louis Bauer, secretary general of World Medical Association, on podium.

California's PG Plan

Nearly 1,500 postgraduate medical training courses are offered to physicians in the United States (see The Journal, Aug. 15, 1959), but in few areas of the country is there such coordination with the practicing physician as exists in California.

At the Second World Conference on Medical Education last month the system was explained by Dr. Phil R. Manning, director of postgraduate education for the University of Southern California's medical school. In this program, initiated by the California Medical Association, practicing physicians are given the opportunity to plan curriculums with the medical school faculty, and they have actually been participating in academic programs with the teachers.

Programs include two-way teaching institutes, circuit courses in rural communities, and annual courses at state scientific meetings. This liaison of the medical educator and the practicing physician, says Dr. Manning, works in a mutually beneficial way for the well-being of all patients. And, he adds, through coordinated activities of the five medical schools in the state, there is an active extramural postgraduate program designed to meet the needs of physicians living in communities away from the teaching centers.

tion and experiences among countries. In this way a treasure-house of ideas and a compendium of knowledge in the broad field of medical education is able to flow from the more advanced countries to those now moving into the full light of medical progress.

—Dr. Louis H. Bauer, New York, secretary general, World Medical Association.

On "progress"—

The two biggest hazards threatening the quality of medical care on the North American continent today are too much dependence on drugs and a preoccupation with the financial aspects of medicine. The fault is not the doctor's alone; in our technological culture the laying on of healing hands has been replaced by instrumentation. Large sections of our people clamor excessively for x-ray examinations, chemical tests, and surgical procedures. Confidence in the healing power of nature has been displaced by undue dependence on the popular drugs of the moment.

—Dr. J. Wendell Macleod, Saskatoon Canada.

On hospital relations—

The void that exists between general practitioners and hospitals has worked to the detriment of the patient. There is no reason why this relation of mutual confidence between the doctor and his patient, which means so much in the treatment and prevention of sickness in the familiar environment, is not similarly valuable in the hospital circle.

—Dr. Juan Allwood-Paredes, El Salvador.

On specialization—

Fostering of medical specialties has encouraged a false method of dealing with the patient: He became during the past decades a "case" of liver, lung, heart, or something else and was no longer a "human," suffering in his body and soul. Even the patient himself cooperates in this change of medical practice, looking for as many specialists as he possibly can.

—Dr. Carlos Gomes D'Oliveira, Lisbon, Portugal.

Surveys of medical societies and placement bureaus reveal that there is approximately five times the demand for competent general practitioners as there is for doctors trained to care for only certain segments of disease. This demand has been largely ignored by some of our medical schools in their headlong effort to satisfy those who advocate impersonal, mass service, production-line medical care.

—Dr. Malcolm E. Phelps, El Reno Okla.

On medical practice—

It is very unfortunate that many of our finest teachers have not had the opportunities of actually practicing medicine outside of the cloistered confines of a huge medical center. If these fine teachers could experience such satisfying contact with a patient they would learn that the ailments seen, the problems presented, and the treatments necessary would be vastly different than those which they are accustomed to seeing in the teaching centers. This experience would not only make them better teachers but would give them an insight into situations that have to be met in the private practice of medicine.

—Dr. Phelps.

Twelve Who Did Not Fail

If the passing grades of state licensure examinations are a gauge of the quality of medical education, then 12 medical schools in the United States stand at the top of the list. The latest report on medical licensure by the A. M. A. Council on Medical Education and Hospitals shows that last year these 12 approved schools had no medical licensing examination failures among their graduates:

Stanford University
Chicago Medical School
University of Chicago
Boston University
Wayne State University
University of Mississippi
University of Missouri
University of Nebraska
Albany Medical College
University of Oregon
University of Pittsburgh
University of Utah

A total of 540 graduates of those medical schools passed examinations given in several dozen states.

Lions, Whales And Doggedness

It took more than a year of transcontinental planning and hard work, but, thanks to the teamwork of a fraternity, a ship's surgeon, and a medical educator, exciting brain research is moving ahead on a relatively unexplored plane. Joining in the cooperative effort were the Norwegian government, a crew of rugged whalers, and a steamship line.

The story begins in mid-1958 when Dr. Arthur V. Jensen, assistant dean and associate professor of anatomy at New York Medical College, spoke to the Croton-on-Hudson Lions Club about a lack of research on the brains of whales. Club members decided that here was a goal in their work to aid medical knowledge (see Medicine at Work, THE JOURNAL, April 25, 1959, for similar Lions Club efforts). They approached fellow Lions in Tonsberg, Norway, where the owner of a whaling vessel, Carsten Bruun, agreed to donate the brains of his catch.

In February and March the ship's surgeon, Dr. David Hummel, was able to take part in the removal of three whales' brains—delicately trimming the skulls with huge power saws so that formalin preservative could be injected. Each time. Dr. Hummel jumped into the blood and muck and used his sheath knife to sever the spinal cord with split-second timing.

The Norwegian-American Line donated the transportation of the specimens to New York Medical College, where the barreled brains were accepted June 25 at a ceremony attended by Norway's acting consul general. Dr. Jensen hopes to do comparative studies involving the human and the porpoise brain, and to observe the correlation between external organs of some special senses—such as smell, vision, and hearing—and the structures in the brains corresponding to those senses.

"This project," says the medical college dean, Dr. Ralph E. Snyder, "has not only aided medical science but has also contributed to cooperation with our friends around the world, through our common desires for learning, culture, and understanding."

A Look at the Future Of Medical Television

Ever since television established itself as a popular medium, its potential as a teaching instrument has interested medical educators. Closed-circuit telecasts have become standard fare at most big medical meetings, and experiments are being made to determine whether commercial channels may also be practical carriers for medical programming.

So far, these ventures have generally been carried on as solo operations, but next week a new organization, devoted to the advancement of medical telecasting, will hold its maiden meeting at Bethesda, Md. Known as the Council for Medical Television, the group is the outcome of a conference on television and postgraduate education held early last spring. Co-sponsors of the conference were the American Academy of General Practice and the Institute for the Advancement of Medical Communication.

Represented at the original conference were six types of organizations concerned with medical education: professional associations, universities, voluntary health agencies, pharmaceutical firms, governmental agencies, and equipment and broadcasting companies. The conferees spent two days deciding what areas promised fruitful study and then authorized formation of the Council for Medical Television within the framework of the Institute. The meeting Oct. 15 and 16 will be the first formal council session.

Although oriented to television as a medium, members of the council believe that it may be able to adapt some methods of other educational pioneers to its own uses. Of particular interest, according to its bulletin, are the two-way FM radio courses now being offered by Albany Medical College (see Medicine at Work, THE JOURNAL, March 21, 1959). The possibility that Albany may soon be joined on the air by other schools offering postgraduate medical education was indicated when the A. M. A. recently filed a petition with the Federal Communications Commission requesting the allocation of six FM channels for medical education purposes.

Miami's Medical School Invites Public Interest in Its Affairs

When a private medical school operates under a state subsidy, uses the facilities of a county-owned hospital, and leases quarters from the Veterans Administration, diplomacy indicates that its aims and ideals be thoroughly understood within its own community.

This is the position of the six-year-old School of Medicine of the University of Miami in Florida whose teaching units are spread throughout Dade County. Seeking to bind itself more closely to the community, the school recently unveiled a plan to bridge the gap between town and gown by means of a 21-man advisory council with a mandate to "concern itself with institutional and financial development of the school and all phases of the school's operation touching on the public interest."

Six local physicians have joined lawyers, bankers, businessmen, and manufacturers on the new council, which is responsible to the school's board of

Committee on Alcoholism of A. M. A. Council on Mental Health meets in Chicago Aug. 14 and 15. At left, back to camera, Chairman Marvin Block discusses with Harold Himwich and Robert Fleming the subjectivity of certain physicians who attempt to diagnose the disease. (Not shown are committee members Selden Bacon and Jackson Smith.) In photo at right, committee guests study details of proposed handbook of alcoholism terminology based on Standard Nomenclature of Diseases and Operations. Guests (left to right) are Dr. E. M. Jellinek of International Institute for Research on Problems of Alcoholism, Mrs. Adaline Hayden and Dr. Edward Thompson of Standard Nomenclature, Mr. Mark Keller of *Quarterly Journal of Studies on Alcohol*, and Dr. Ruth Fox of National Council on Alcoholism.

trustees. The idea for such a council emerged from a meeting between the school's dean, Homer F. Marsh, Ph.D., and Dr. Milton Coplan, clinical professor at Miami (and Chairman of the A. M. A. Section on Urology). Dr. Coplan has been interested in the school since its inception and has aided in developing its faculty.

The school's trustees approved the council idea last December and appointed the first 12 members late in February. The council now has a full roster and has met several times. Physicians appointed include Drs. Coplan, E. Sterling Nichol, Warren W. Quillian, Donald W. Smith, S. Charles Werblow, and Kenneth S. Whitmer.

The school's biggest current problem is the financing of a $4 million dollar medical education and research center. Students now travel as far as 23 miles between elements of the school housed in such varied facilities as an abandoned naval base, the ballroom of a former luxury hotel, and a funeral parlor.

Atom Lab—Challenge in Occupational Medicine

One of the most formidable responsibilities in the field of occupational health is that held by Dr. Thomas L. Shipman, who daily faces the task of supervising the work environment of hundreds of employees in an area where disaster may follow one false move.

Dr. Shipman is health division leader of the Los Alamos (N. Mex.) Scientific Laboratory, and the program he maintains in one of the world's most ticklish "industries" naturally interests the A. M. A. Council on Industrial Health. Next week the Council members will get a firsthand briefing at Los Alamos. The session, Oct. 15 through 17, will combine a regular meeting of the Council with a tour of the laboratory and an explanation of its preventive health program.

Agenda items include:

—Proposed revisions of the Council's policy

Physician to a Factory

Can a physician in private practice logically look on a small industrial concern as a "patient"? He can indeed, and in quite a number of instances he does—to the benefit of both himself and the workers.

Suspecting that an indeterminate number of small plants (with 500 employees or less) are operating occupational health programs under the leadership of a doctor who devotes only part of his time to the task, the A. M. A. Committee on Medical Care for Industrial Workers recently completed a spot check. Its report states, "Results of the survey confirm the Committee's belief that the physician in private practice can [supervise and administer] such programs. Whether the physician practices by himself or as part of a group, the survey findings reveal that all, or a wide range of, occupational health services can be provided to employees in small establishments."

The report, which goes to the Council on Industrial Health, is based on 200 replies to a questionnaire mailed to physicians thought to be engaging in such work. The purpose of the poll is based on this Committee belief: "Thousands of additional physicians, if they are aware of the nature of the programs and the roles they can assume in supervising them, could be encouraged to take a greater interest in the development and expansion of such services. . . ."

Is there a need for such development and expansion? Unquestionably, says the Committee, noting that the "overwhelming majority" of small plants do not make such programs available to their employees, who make up approximately 80% of the nation's labor force.

statement, "Scope, Objectives, and Functions of Occupational Health Programs."

–Consideration of possible sites for the 1961 Congress on Industrial Health. (The 1960 session is scheduled for Charlotte, N. C.)

–Reconsideration of statements on executive health examinations and multiphasic screening developed by the Committee on Medical Care for Industrial Workers (see Medicine at Work, THE JOURNAL, April 25, 1959).

As the Council prepares to meet, members recall that it was on New Year's Day, 1959, that a technician died of overexposure to ionizing radiation. The fact that this was the first serious case of radiation injury at Los Alamos since 1946 indicates the care exercised by Dr. Shipman and his fellow workers.

Doctor-Teacher Seminars On Health in Education

Five of the most significant issues in school health and physical education will get a thorough airing next week at the National Conference on Physicians and Schools in Highland Park, Ill.

Approximately 300 physicians, educators, and public health workers are expected to attend the session, the seventh such affair to be sponsored by the A. M. A. Department of Health Education. They will listen to guest experts, join in small discussion groups, and express conclusions on Oct. 13, 14, and 15. Topics chosen for timeliness and significance include:

Fitness. Should young people be rated on national physical performance norms as derived from tests?

Teaching. How much time is needed, and where, in the crowded curriculum, can you find it for health education as well as physical education?

Examinations. Do periodic health examinations pay off, in terms of the medical manpower they require?

Standards. Are they needed at each grade level to measure health knowledge, attitudes, and behavior?

Classification. How can pupils be categorized for physical education purposes, and how can the problem of medical excuses be alleviated?

Past conferences have been truly national in scope, with all states represented, but this year even the international character of health education will be demonstrated, when Dr. I. H. Flack, editor of the British magazine *Family Doctor,* speaks on "Problems of Communication in Health Education."

The AHA Annual Meeting

Highlights Focus on Osteopathy, Costs, Warmth, and Physicians

Hospitals need more help from physicians in day-to-day management—and at the same time physicians need to recognize the dangers of controls on hospitals. Dr. Russell A. Nelson, director of the Johns Hopkins hospital, Baltimore, has sounded that double challenge in his induction speech as president of the American Hospital Association:

"The public and its insurance companies are sensitive to problems of utilization. Doctors admit and order services on patients, and only they can make these judgments—only they can exercise any control. Hospital doctors need more responsibility and authority in hospital affairs. . . . By and large, the medical profession has not yet realized the implication to medical practice inherent in the controls of cost and use. Too often there are private murmurs that something is wrong 'in Blue Cross and the hospitals.' They don't stop to think that controls on use of beds and services are controls on their medical judgments and that controls on hospital costs put a limit on hospital services to their patients. We must make the profession see the dangers and work with us on solutions."

As Dr. Nelson spoke to the AHA's 100 delegates, more than 12,000 hospital officials were attending exhibits and other sessions at the 61st annual meeting in New York City late in August. Among actions taken by the delegates was one to permit AHA listing of hospitals where osteopaths are practicing under supervision of doctors of medicine.

A total of 48 AHA program sessions covered a wide range of topics, including progressive patient care, employee relations, accreditation, and prepayment plans for the aged.

One panel agreed that the answer to health care for the aged must come through cooperative community planning in which health facilities are but one important factor in the search for ultimate solutions. Said Kenneth J. Holmquist, a panelist who is superintendent of the Bethesda Hospital in St. Paul, Minn., "Because the aged have such a great variation in their health needs and because most of them can be cared for in their own homes, the importance of extending the hospital services to their own homes or to a related health facility becomes of major importance."

In two other sessions a noted public opinion analyst and a psychiatrist stressed the need for more warmth to hospital patients and a higher level of emotional maturity among hospital em-

Family Underground—A Test in Confined Living

Where do you find a family of five willing to spend two weeks in a bomb shelter as an experiment in confined living? If you're as lucky as members of the psychology department at Princeton University, you find them right under your nose.

Thomas A. Powner, a manual training teacher who does part-time work for the university, volunteered the services of himself, his wife, and their three children when he learned of the need. They emerged from their self-imposed isolation in mid-August after having spent 14 days in an 8-ft. by 9-ft. fall-out shelter, in a test, sponsored by the university and the Office of Civil and Defense Mobilization, to assess the stresses of confined living. The shelter was located in the basement of a university building.

The Powners lived on canned food, bottled water, and air circulated by means of a hand-cranked ventilator. For illumination they had candles and a flashlight; the candles served double duty by heating food. For recreation there were games for the kids, all under 5 years of age, and books for the adults. They also had a bottle of whisky and a supply of tranquilizer pills.

The Powners' pediatrician, Dr. S. Robert Lewis, examined all the children before and after the experiment and provided Mrs. Powner with a set of written instructions for maintaining their health during isolation. No serious difficulties were encountered during the stay, which the family could have ended at any point. All lost weight except one of the children, who gained.

Chief among the Powners' problems were poor ventilation, overheating, and waste disposal, but even at that Mrs. Powner says, "It wasn't as bad as I thought it was going to be."

One thing did alarm the family, however. When they emerged, they were told that a hidden microphone had permitted tape recording of every sound made during the isolation test—a safety precaution decided on by scientists conducting the experiment.

ployees. "People have great admiration for the hospitals' technical facilities and performance but feel the human side of hospital care is frequently given short shrift," said Elmo Roper. And Dr. Francis J. Braceland, psychiatrist-in-chief at the Institute of Living, Hartford, Conn., told another AHA audience, "The emotional immaturity of hospital personnel is the primary hindrance to efficient hospital operation and effective service to patients." Dr. Braceland called on hospital personnel and the 2 million volunteers working in hospitals to shed the "egocentricism of infancy, the balkiness and unreasonableness of youth, and take a close look at ourselves."

Not immaturity but carelessness appears to be the major cause of financial losses to hospitals from malpractice suits, according to Dr. August H. Groeschel, associate director for professional services at New York Hospital, where 389 errors in administration of medicaments were recorded last year. This is an average of one medication error out of 17,000 administrations. At least four out of every five of the mistakes, says Dr. Groeschel, occurred during peak busy hours when nurses were so rushed they misread or misheard prescriptions.

A lighter note on an equally serious subject was sounded at a panel discussion which concluded that there should be a closer integration of the "allied health professions" in hospitals. Abe Rubin, D.Sc., secretary of the American Podiatry Society, said, "The fact that the average patient being given a physical examination in a hospital is asked to remove all clothing except his shoes is recognition of the podiatrist's special field."

Babies, Aged, and Public Health Are Only Part of CMS Report

In 1950, an A. M. A. House of Delegates policy statement listed six basic services to be provided by public health authorities: vital statistics, public health education, environmental sanitation, public health laboratories, communicable disease control, and maternity and infancy hygiene where private facilities are unavailable. This year the Council on Medical Service launched a study designed to reevaluate the 1950 statement in the light of present conditions.

In its annual report—discussed at a meeting held in Chicago Aug. 29 and 30—the Council notes that the "basic six no longer approximate the sum total of public health concern. In addition to these traditional services, many public health authorities are now interested in diabetes control, cancer control, rheumatic fever prophylaxis, indigent medical care, mental health, heart disease, and accident prevention."

Objectives of the current study being undertaken by the Council's Committee on Medical Facilities are to inventory public health services and to redefine the relationship of public health to private practice.

Here are some additional highlights from the reports of other committees of the Council:

—A prospectus for current and future activities has been drawn up by the Committee on Indigent Care. It outlines activities which the Committee feels it ought to undertake to implement its belief that "the profession should work actively, formally, and publicly to assure the adequate, high-quality care for the needy demanded by A. M. A. policy statements."

—The report of the Committee on Maternal and Child Care reviews conferences which preceded the Committee's publication of "A Guide for the Study of Perinatal Mortality and Morbidity" in April, a supplement to which is now being prepared. Current and future activities in this field will be aimed at helping to solve the many problems of the perinatal period.

—The Committee on Medical Care for Industrial Workers reports that a change for the better in relationships between the A. M. A. and representatives of union health plans seems to have become evident since the issue of the report of the Commission on Medical Care Plans. It also suggests that this affords "a splendid opportunity for the resolution of some of the problems certain states have encountered in their relations with . . . medical care plans."

—A state-by-state recapitulation of health insurance programs for elderly persons is a feature of the report of the Committee on Insurance and Prepayment Plans. It follows a detailed analysis of the growth, in the past year, of medical insurance coverage in the U. S.

—The Committee on Federal Medical Care reports its efforts to aid the Railroad Retirement Board in getting satisfactory physical examination reports from private physicians in a greater proportion of its disability cases. In the past, federal and state medical facilities have sometimes been used for such examinations.

—A series of nine regional conferences on aging are now under way, according to the report of the Committee on Aging. Three have already been held. The remainder will take place during the coming six months. Directed toward lay groups interested in aging, as well as medical and related organizations, the meetings have featured speakers, panels, and symposiums. Subjects covered include employment and retirement policies, financing health care, and such expanding developments as home care, homemaker services, and progressive patient care experiments (see Medicine at Work, THE JOURNAL, Sept. 12, 1959, and April 26, 1958).

How Doctors Tutor the Careless To Cut Ohio's Auto Injuries

The arms of many former infantrymen still bear small, circular scars as a result of a World War II training device—a drop of mustard gas placed on the skin. The resulting burn taught a long-lasting respect for the potency of chemical weapons.

Today, more than 15 years later, a variation of the same technique is being used by physicians in Akron, Ohio, to impress careless drivers in the different—but no less deadly—war against accidents.

The Ohio physicians use colored slides, x-ray films, and tales of the emergency room in a "school" to which law-breaking motorists are often sentenced by Akron judges. The purpose is to develop a respect for the carnage that can be wrought by a ton and a half of highly powered steel in the hands of a driver who either forgets safety rules or thinks they are for squares.

Dr. Paul Weygandt, chairman of the Summit County Medical Society's safety committee and a member of the school's faculty, described the plan at the annual A. M. A. Public Relations Institute in August. He said, "We use some pretty graphic examples because our captive audience usually has flat-top haircuts and requires a little shocking." Drivers are assigned to the school as a part of the sentence for traffic violations. The judge makes it plain that attendance can easily be replaced by 30 days in the workhouse. Attendance is controlled by means of enrollment slips that are stamped at each session.

Violators attend four sessions in all, one of which is given by the physicians, four orthopedists and a surgeon. The other three are offered by representatives of the highway patrol, the insurance companies, and the judiciary. The course takes four days, with one 45-minute session devoted to a single subject each evening.

The school originated in 1953, when Judge Thomas Powers of the Akron Municipal Court prevailed on the local Junior Chamber of Commerce to assume its operation, but it wasn't until last year that the Summit County Medical Society added the fourth lecture on injuries to the original three, which dealt with the law, financial responsibilities, and driving techniques. "These folks are a challenge," says Dr. Weygandt in what is undoubtedly an understatement. "We try to emphasize the suffering and expense caused by traffic injuries—not just deaths." Results, of course, are hard to document, but the doctors note that few have to take the course a second time.

Perhaps the school's greatest tribute came from the parents of one offender who had been forced to attend. They wanted to know if another child—about to begin his driving career—could enroll too.

The Doctor-Pilots

They Fly for Fun, but They Form a Mobile Disaster Force, Too

Richard P. Pratt

It was a bright spring day in mid-April, 1947, when the freighter *Grandcamp*, berthed at a Gulf Coast pier, exploded, caught fire, touched off a conflagration that took 500 lives, and engraved the name of Texas City high on the list of man-caused disasters.

More than 12 years later, the nightmare impression of that flame-lit tragedy is a constant symbol of purpose to Dr. Frank Reed as he lays detailed plans for mobilizing Illinois' airborne physicians in the event of a similar disaster. Today Dr. Reed is disaster chairman for Illinois of the Flying Physicians Association, but on that tragic day in 1947 he was an Army medical officer undergoing indoctrination at Fort Sam Houston. Flown to Texas City as one of a team of Army physicians, he has a vivid and personal knowledge of the value of a trained and instantly mobile medical team in time of catastrophe (see Medicine at Work, THE JOURNAL, Aug. 10, 1957).

Dr. Reed's dream—and that of the other doctor-pilots who form the membership of the four-year-old Flying Physicians Association—is an organizational plan that will make any or all of the airborne medicos almost instantly available to aid the sick and injured in emergencies of any magnitude. The FPA's proposed disaster service is the brainchild of Dr. Frank Coble of Richmond, Ind., who explains it this way:

"The Flying Physicians Association has 1,500 members, each of whom could quickly pick up one or two nurses from his office or local hospital and a bundle of medical supplies on short notice. Since each doctor flies his own plane, no other pilots are needed. These planes are capable of landing in a cow pasture or on a segment of blockaded highway.

Although the disaster plan is still chiefly a paper one, Dr. Coble has high hopes that other areas will follow the Illinois lead in organization, and that in time the nation will be spanned by a network of interconnected FPA disaster groups.

Safety at the Stick

Last June the FPA demonstrated its ability to mobilize a group of doctor-manned planes and fly them thousands of miles to a predetermined location, when 52 of its members took part in an air cruise to Anchorage, Alaska. Starting from all regions of the U. S., the doctor-pilots—many with friends or family members on board—met in Great Falls, Mont., and followed the Alaskan Highway to the 49th state. A similar, if somewhat less spectacular, performance was held last month when hundreds of FPA members zeroed in on Wagoner, Okla., for the group's annual meeting.

Emergency planning is the most ambitious project yet undertaken by the FPA, but it is by no means the only activity. Flying proficiency and safety are crucial matters that have been forced on the physician-pilots by necessity. Alarmed by fatal but avoidable "weather" accidents, the doctors have made minimum instrument training a requirement for membership renewal. Required is the ability to make a 180-degree turn while "in the soup" and to maintain a straight and level course. Put together, these two skills are sufficient to enable the pilot to fly back out of instrument weather into which he may have ventured inadvertently.

An apostle of such flying safeguards is Dr. Harold N. Brown of Lombard, Ill., national FPA safety chairman. A former flight surgeon and Air Force pilot, he not only preaches instrument safeguards to his brother physicians but bombards popular flying magazines with articles on such subjects as oxygen deficiency and depth perception in aviation. Flying safety is a family affair. Mrs. Brown is also a physician, and a flying one at that.

The Aerial Practice

Although most of the flying physicians fly only as a hobby, or perhaps to medical meetings, some have used private air transportation to expand their practices:

—In the Hawaiian Islands, Dr. William Totherow services a distant and doctorless village on the island of Maui, from his home base at Wailuku, by commuting three days a week in his own plane.

—In Alaska, Dr. Milo Fritz uses his Anchorage-based plane to visit patients in outlying areas and

And the Earth Trembled

Although neither of them is a pilot, two Montana physicians made good use of planes as emergency transportation this year when the mid-August earthquakes killed and injured scores of vacationers in Yellowstone National Park. Drs. Raymond G. Bayles of Bozeman and Ronald Losee of Ennis both chartered aircraft to speed aid to the injured.

Dr. Bayles flew to the Hebgen Dam area and then switched to a boat across the lake to a point where a large group of the injured had gathered.

Dr. Losee was faced with a dual problem. First he helped evacuate his own small town of Ennis which was threatened with inundation by the weakened dam. Later he flew to the site of a tremendous landslide to treat survivors and see to their hospitalization.

Working under pressure, physician (left, in white shirt) cares for victims of recent Montana earthquake as they patiently wait for planes that will fly them to hospital.

to ferry them from remote villages to city hospital facilities.

Not all working flyers live in the more exotic areas of the nation, either. In downstate Illinois, Dr. William Requarth leaves his Decatur office each Wednesday for a day at the University of Illinois College of Medicine, in Chicago, where he is assistant professor of surgery. And in Milwaukee, Dr. Herman Heise, who is Chairman of the A. M. A. Committee on Medicolegal Problems, uses his plane in atmospheric tests of pollen distribution and fall-out probabilities.

It was in Chicago, too, that two flying doctors recently proved how valuable the marriage between medicine and aviation can be: A Michigan physician, faced with a patient whose heart had stopped beating on an average of every five minutes for more than 24 hours, needed electronic equipment to take over the job of heart stimulation that had to be done manually in the small hospital. To the rescue came two Chicago flying physicians who not only flew the patient to downtown Meigs Field, but kept him under constant medical observation during the critical hop.

Kitty Hawk to the Moon

Both flying itself and the attendant problems have fascinated doctors for some time. Wilbur Wright had hardly got off the ground at Kitty Hawk before medical men began to take an interest in the problems posed by man in flight. The late Col. David A. Meyers was one of the early doctor-pilots in the era of the Jenny and the Liberty engine. He not only served as chief surgeon of the early Air Corps, but was also co-inventor with Col. W. C. Eaker of the turn and bank indicator, still a basic flight instrument. One of Colonel Meyers' chief interests was in the physiology of flying, although he probably little realized that such studies would one day hold the key to man's efforts to project himself into space (see Medicine at Work, THE JOURNAL, June 15, 1957).

Although most of today's physicians fly for pleasure, the profession has long recognized the medical advantages inherent in such a fast and efficient form of transportation. In Australia, settlement of the forbidding interior of the continent has been made incalculably safer by the Flying Doctor Service, which covers an area of 2 million square miles from 12 bases. Nearly every lonely outpost maintains radio contact with the service originated by a medical missionary, the Rev. John Flynn, and now operated by the Australian government.

The Soviet Union claims to have served 85,000 of its isolated citizens last year through health squads using airplanes, helicopters, and automobiles. And in Portugal, the new Minister of Health, Dr. Martins de Carvalho, is planning helicopter-equipped teams to provide medical relief to accident victims in rural areas.

Although most flying doctors are hearty advocates of air travel for their professional brethren, there are a few with complaints—some of them humorous only in retrospect. One physician, flying to the hospital with a patient in labor, found that with each contraction she stiffened, kicking the rudder bar and putting the plane into a skid. Despite the handicap, both the flight and the subsequent delivery were successful.

Skills and Mobility

"The flying physician represents an unusual combination of skills—a physician with facilities to move quickly to a stricken area. . . . He represents an important resource of medical skills."

The speaker is Dr. Harold Lueth, Chairman of the A. M. A. Committee on Disaster Medical Care and a consultant to the Office of Civil and Defense Mobilization. The occasion is the meeting in Anchorage, Alaska, last June of more than 50 flying physicians who flew their own planes to the northern state.

Dr. Lueth told the group about civil defense plans for the medical care of mass casualties and quoted OCDM Director Leo Hoegh on citizen responsibility: "Civil defense, to be effective, will involve every human being, professional or nonprofessional, and every facility that can be found."

GRADUATE MEDICAL EDUCATION IN THE UNITED STATES

ANNUAL REPORT AND DIRECTORY OF APPROVED INTERNSHIPS AND RESIDENCIES IN THE UNITED STATES; AND THE REQUIREMENTS OF EXAMINING BOARDS IN THE MEDICAL SPECIALTIES. PREPARED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

John C. Nunemaker, M.D., John Hinman, M.D., Willard V. Thompson, M.D., and Helen Neitzel

ANNUAL REPORT

The 33rd Annual Report on Internships and Residencies is submitted herewith, consisting of detailed information and statistical data on all intern and residency programs approved by the Council.

Its primary purpose has always been to provide this information for recent medical school graduates who wish to continue their subsequent medical education and clinical training as interns or residents. While this information applied almost exclusively to graduates of United States and Canadian medical schools prior to 1948, it has subsequently become of world-wide importance to the many graduates of foreign medical schools wishing to learn American methods for application in their homelands.

A secondary and increasingly important function of this report is the use made of it by those responsible for administration of medical care and training programs and for planning for the future. Such persons represent hospital administration, medical school administration, state medical boards, editorial staffs of professional as well as lay journals, and government agencies such as the Department of State, the Military Establishment, and the Veterans Administration.

This annual report consists of three major portions—the statistical tables and narrative analysis of program performance and trends, the Directory of Approved Internships and Residencies, and the Requirements for Certification of the American Specialty Boards. The entire report is reprinted as the Directory of Approved Internships and Residencies, and is available upon request to the Council.

The statistical analyses on internship programs follow the format of previous years, but for residency programs considerable additional data were secured in a supplementary questionnaire which was satisfactorily completed by a majority of the hospitals. A chart has been prepared which demonstrates the remarkable post-World War II increase in graduate training programs, particularly residencies, and it includes the programs supported by federal agencies as well as the positions filled by foreign medical graduates. Additional data on foreign medical graduates have been generously provided by the Institute of International Education.

The Directory of Approved Internships and Residencies represents the cooperative efforts of three groups. The Council staff maintains a year-round program of surveys and consultations at the hospital level; the medical staffs and administrators of the hospitals listed cooperate fully in providing the necessary data for both the surveys and for the annual questionnaire; the Review Committees evaluate the survey reports and also determine the future status of programs and appropriate methods of listing approved programs in the Directory.

The functions and responsibilities of the various Review Committees were described in detail in the 32nd Annual Report published in The Journal of the American Medical Association Oct. 4, 1958. The following organizations collaborated with the Council through representation on the Internship Review Committee:

- American Academy of General Practice
- American Hospital Association
- Association of American Medical Colleges
- Federation of State Medical Boards of the United States

The following organizations collaborated with the Council in approving residency training programs:

- Advisory Board for Medical Specialties
- American Academy of General Practice
- American Academy of Occupational Medicine
- American Academy of Pediatrics
- American Board of Anesthesiology
- American Board of Dermatology
- American Board of Internal Medicine
  - Subspecialty Board on Allergy
  - Subspecialty Board on Cardiovascular Disease
  - Subspecialty Board on Gastroenterology
  - Subspecialty Board on Pulmonary Diseases
- American Board of Neurological Surgery
- American Board of Obstetrics and Gynecology
- American Board of Ophthalmology
- American Board of Orthopedic Surgery
- American Board of Otolaryngology
- American Board of Pathology
- American Board of Pediatrics
  - Subspecialty Board of Pediatric Allergy
- American Board of Physical Medicine and Rehabilitation
- American Board of Plastic Surgery
- American Board of Preventive Medicine
- American Board of Proctology

For the detail work in preparing the lists of internships, residencies, and the specialty Board requirements, the Council staff is especially indebted to Miss Catherine Hayes, Mrs. Mildred Kaiser, and Mrs. Rose Tracy.

American Board of Psychiatry and Neurology
American Board of Radiology
American Board of Surgery
American Board of Urology
Board of Thoracic Surgery
American College of Physicians
American College of Surgeons

While the Council does not approve internship or residency training programs in Canada, the Directory includes the list of hospitals in the Dominion of Canada with internship programs approved by the Canadian Medical Association.

The Requirements for Certification of the American Specialty Boards contain the essential information found in the special booklets published by the majority of the boards although certain historical data about each board have been omitted. Tables reveal the total certificates awarded in each specialty and the cumulative totals to June 30, 1959.

Internship

The slowly progressive increase in number of internship positions and the number of hospitals having approved internships is revealed in table 1. For the intern year 1958-1959, 12,469 positions were offered, representing an increase of slightly more than 1% over the preceding year. At the same time, the hospitals offering such training decreased from 867 to 853 with the result that the average number of positions per hospital is 14.6, the highest in the past ten years.

Internships, by Type of Service

The following three types of internships are approved by the Council: (1) rotating, which includes training on the medical, surgical, pediatric, and obstetric services; (2) mixed, providing training in two or three of the four major clinical services named above; and (3) straight, providing training on a single medical, surgical, pediatric, obstetrics-gynecology, or pathology service. Straight internships are approved only in hospitals having approved residency programs in the specialties concerned. Because a hospital may offer more than one type of internship, there are accordingly 1,099 approved internship programs in 853 hospitals. The relative distribution of internships according to type reveals that 75% of the programs offer rotating internships, 3% of the programs offer mixed internships, and 22% of the programs offer straight internships. Of the total internship positions available, 87.3% are rotating internships, 1.4% are mixed, and 11.2% are straight internships.

TABLE 1.—*Number of Internships, 1950-1959*

	No. of Hospitals	No. of Internships
1950	799	9,398
1951	828	10,044
1952	865	11,467
1953	856	11,006
1954	844	10,624
1955	850	11,618
1956	867	11,616
1957	852	11,895
1958	867	12,325
1959	853	12,469

TABLE 2.—*Number of Internships, by Type of Service, 1958-1959*

		No. of Internships		
Type of Internship	No. of Approved Programs	Filled Sept. 1, 1958	Vacant Sept. 1, 1958	Percentage Filled
Rotating General	805	8,935	1,882	83
Other Rotating	17	64	9	88
Totals	822	8,999	1,891	83
Mixed	38	166	13	93
Straight				
Internal Medicine	72	593	81	88
Surgery	68	360	60	86
Pediatrics	55	162	46	78
Pathology	34	59	19	76
Obstetrics and Gynecology	10	13	7	65
Totals	239	1,187	213	85
Grand Totals	1,099*	10,352	2,117	83

* Number of approved intern training programs in 853 hospitals.

Table 2 reveals the distribution of internships according to type and reveals the occupancy for each type on Sept. 1, 1958. Rotating internship positions were 83% filled, mixed internships were 93% filled, and straight internships were 85% filled. As in previous years, straight internships in internal medicine showed the highest rate of occupancy, 88%. Straight internships in obstetrics and gynecology were only 65% filled, but this category was added to the approved list only last year.

Of the total of 12,469 internships, 10,352 were filled and 2,117 were vacant. The percentage filled, 83%, is the identical figure for the past four years.

Internships, by Type of Hospital Control

Table 3 classifies internships according to one of the four major types of control. While there was a decrease in the number of nongovernmental hospitals compared to last year, they still comprised the largest group at 673, or 78.8%. The nonfederal governmental hospitals again totaled 133, or 15.5%. Federal hospitals decreased from 41 to 39, comprising 4.5%; and the proprietary hospitals decreased to 8, or 1% of the total.

As of Sept. 1, 1958, the federal hospitals showed the highest occupancy rate at 93%, while the rate in the proprietary hospitals was lowest at 75%.

While internships in the uniformed services of the federal government revealed almost 100% occupancy in all instances, it is apparent the very small number of internships in the Veterans Administration are not popular, since only 44% of the positions offered were filled on Sept. 1, 1958.

The average number of interns on duty in each of the four major groups is for federal hospitals, 15.1; governmental, nonfederal, 24.5; nongovernmental, 9.5; and proprietary, 5.5; with the overall average of 12.1 interns on duty per hospital.

While for the past four years there has been a steady increase in the number of intern positions filled to a high figure of 10,352 positions filled in 1958, the percentage filled has remained steady at 83%.

Table 3.—*Number of Internships, by Type of Hospital Control 1958-1959*

Control	No. of Hospitals	No. of Internships: Filled Sept. 1, 1958	Vacant Sept. 1, 1958	Percentage Filled
Federal				
U. S. Army	10	239*	1	99
U. S. Navy	14	176	0	100

Grand Totals	853	10,352	2,117	83

---

* Includes 60 positions assigned to the U. S. Air Force.

Internships, by Medical School Affiliation and Bed Capacity

Table 4 represents the simplification of a similar table published in past years in that it distinguishes between those affiliated with medical schools and those not affiliated with medical schools and makes no attempt to divide the affiliated hospitals into those which are major hospitals and those which are minor hospitals in relation to responsibility for teaching undergraduate medical students.

This table reveals the popularity of internship appointments in affiliated hospitals. Of the total of 853 hospitals having approved internship programs, only 190 or 22% were affiliated with medical schools. Positions in these affiliated hospitals were 87% filled in contrast to only 81% occupancy in the nonaffiliated hospitals. Twenty-two percent of the total hospitals thus offered 37% of the total positions and secured 39% of the available interns.

For the nonaffiliated hospitals, only 43% had more than 300 beds, while for the affiliated hospitals, 71% were above 300 beds in size. Using percentage of appointments filled as a criterion, the most popular appointments were in the 67 affiliated hospitals with over 500 beds where their percentage occupancy on Sept. 1, 1958, was 90%.

Internships, by Census Region and States

Table 5 indicates the distribution of internships by state and by census region, and the only change in arrangement from last year was the inclusion of Hawaii in the Pacific region.

As was true last year, hospitals in the New England area led the list with 90% of the internship positions filled on Sept. 1, 1958. Both the Mountain States area and the Pacific States area followed close behind with 89% occupancy rate in each region. As was true last year, the East-South Central region had the lowest occupancy rate of 70%. The states having the lowest rates were Montana, Indiana, Alabama, and Oklahoma. The states with a rate of 90% or greater were Connecticut, Massachusetts, New Hampshire, Vermont, New Jersey, New York, District of Columbia, South Carolina, Colorado, New Mexico, Utah, Hawaii, and Washington.

As was true in past years, the three Middle Atlantic states of New Jersey, New York, and Pennsylvania are responsible for more than one-fourth of the internship training activity in the nation since these states had 26% of the hospitals, offered 26% of the positions in approved programs and secured 28% of the applicants as of Sept. 1, 1958.

Table 4.—*Number of Internships, by Medical School Affiliation and Bed Capacity, 1958-1959*

Classification	No. of Hospitals	No. of Internships: Filled Sept. 1, 1958	Vacant Sept. 1, 1958	Percentage Filled
Nonaffiliated				
Less than 200 beds	121	660	152	81
200-299	255	1,846	521	78
300-499	213	2,256	569	80
500-over	74	1,543	266	85

The states of Idaho, Nevada, and Wyoming continued to offer no internship training programs in their hospitals.

Autopsy Rates

Table 6 lists those 20 federal and 20 nonfederal hospitals having the highest autopsy rates for the past year. These are hospitals having approved internship programs, and do not include hospitals having only approved residency training programs.

The autopsy rate is one useful indication of the "academic climate" in a hospital and reflects the interest of the staff in medical education and in the scientific progress of medicine. While the minimum acceptable autopsy rate is 25%, the Council expects no hospital to be satisfied with a rate maintained at this minimal figure. A rate below this figure may be the basis for withdrawal of approval.

For each group, both the federal and nonfederal hospitals, 14 of the 20 were listed last year.

Internship Stipends

For the year 1958-1959, there was a cessation of the steady increase in monthly stipends apparent since 1954. The federal hospitals were not included in calculations of stipends, and these studies pertained to the 805 nonfederal hospitals reporting stipends.

For affiliated hospitals, the average cash stipend per internship for the year beginning July 1, 1958 was $155, a figure identical with the year before. For nonaffiliated hospitals, the average monthly cash stipend was $198, a figure essentially identical with the rate of $197 for the previous year. The average stipend paid by the nonaffiliated hospitals was accordingly $43 more, on the average, than that paid by the affiliated hospitals.

The graph in figure 1 showing maximum monthly internship stipends in increments of $50 reveals that both the affiliated and the nonaffiliated hospitals have a range of stipends showing very similar distributions while the peak for the affiliated hospitals again shows a maximum rate approximately $50 lower than the peak for the nonaffiliated hospitals.

Data on maintenance were available for 804 of the nonfederal hospitals and revealed that in addition to the higher stipends, a higher proportion of the nonaffiliated hospitals provides full maintenance, 81%, than provided by the affiliated hospitals, 66%. A lower proportion of the nonaffiliated hospitals provides partial maintenance, 16%, compared to that provided by the affiliated hospitals, 25%. While only 3% of the nonaffiliated hospitals provided no maintenance, 9% of the affiliated hospitals provided no maintenance. Of the total 804 hospitals offering approved internships, 78% provided full maintenance, 18% partial maintenance, and 3% no maintenance. The Directory of Approved Internships indicates the monthly stipend, and the letters FM and PM indicate whether full maintenance or partial maintenance is provided in addition to the stipend.

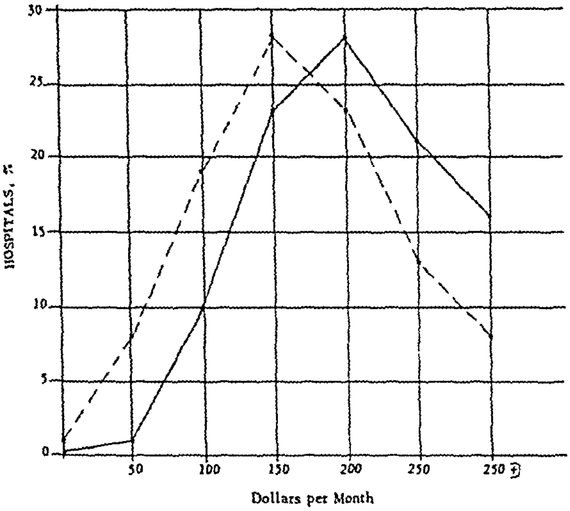

Fig. 1.—Monthly internship stipends for nonfederal hospitals. Solid line indicates nonaffiliated hospitals (627), dashed line, affiliated hospitals (177). Abscissa gives upper level of stipend range.

National Intern Matching Program

The operation of the National Intern Matching Program was fully discussed in last year's annual report referred to earlier. The NIMP is an independent corporation governed by a board of directors with representation of the American Hospital Association, American Medical Association, American Protestant Hospital Association, Association of American Medical Colleges, Catholic Hospital Association, Student American Medical Association, and liaison membership from the federal services having hospital internship programs. The offices of the NIMP are located at 2530 Ridge Ave., Evanston, Ill., and the executive secretary is Ward Darley, M.D. The report of the Seventh National Intern Matching Program was published in January, 1959, in the *Journal of Medical Education,* The Journal of the American Medical Association, and the New Physician. The NIMP performs a very valuable service to hospitals and interns through its matching mechanism, but is also accumulating research data of considerable interest. Several observations from the Seventh National Intern Matching Program Report are emphasized here:

1. The quota saturation percentage for the affiliated hospitals has been increasing and is more favorable than that for the unaffiliated.
2. While more hospitals are offering higher stipends, the increasing high quota saturation for the low as compared with the high stipend hospitals shows that increasing numbers of graduates are attracted to an internship by factors other than stipend.
3. Those hospitals with intern quotas of 20 or more are experiencing a much higher quota saturation than those with less.
4. Without considering the federal services, approximately one-half of the graduates intern outside the state in which their school of graduation is located, one-fourth intern in the hospitals affiliated with their school of graduation, and the other fourth leave the hospitals of their school of graduation but still remain in the state.

The results of the Eighth Annual National Intern Matching Program were published in March, 1959 and showed that there were 12,250 internships to be filled through the plan and 6,478 students matched in the plan. Internships unfilled through the matching plan were therefore 5,772. The number of foreign graduates participating in the matching program for 1959 was sharply reduced because of the requirement for certification by the Educational Council for Foreign Medical Graduates, and as a consequence the total number of interns matched is less than for the previous year. After this year it is expected the number of participating foreign graduates will again be increased.

Foreign Medical Graduates

The Council relies completely on the annual census of foreign interns and residents secured by the Institute of International Education, One East 67th Street, New York 21, New York. For the year 1958-1959, approximately 85% of the hospitals with approved programs reported on the degree of participation of foreign physicians in their training programs. For next year, the census blanks of the

IIE are being mailed with the Council's annual questionnaire in an effort to secure 100% cooperation from the hospitals concerned. The data for those hospitals reporting indicated that for the year 1958-1959, 2,315 foreign medical graduates served as interns in approved training programs.

Residency Training Programs

The first portion of this report on residency programs follows the format of previous years. This will be followed by new information secured in the supplementary questionnaire as well as additional information on foreign medical graduates and the status of graduate training programs since World War II.

Residencies by Specialty

Table 7 differs from the format in previous years only in that the data for hospital specialties precede those in preventive medicine (aviation medicine, occupational medicine, and public health) which are not conducted primarily in hospitals. This table reveals the total number of appointments for each specialty, the number of first year appointments, and the proportion of each filled on September 1, 1958. The number of approved programs increased from 5,299 for 1957-1958 to 5,433 for 1958-1959. The total number of residency positions offered increased by 4% to 31,818. Of this number, 11,239 or 41%, were first year residencies.

Training is offered in 28 specialties including general practice and pediatric allergy. The specialty offering the largest number of residency positions was surgery with 5,837; this was followed by internal medicine with 5,606. In last year's report, obstetrics and gynecology was erroneously reported as holding third position. Actually, psychiatry held third position last year and again this year with 3,542 residencies. Pathology was in fourth position with 2,643 positions; and obstetrics and gynecology was in fifth place with 2,600 positions. The positions offered by these five specialties account for nearly two-thirds of the total number of residencies. An occupancy rate of 90% or higher was shown for aviation medicine, cardiovascular disease, dermatology, obstetrics and gynecology, ophthalmology, pediatric allergy, and surgery. The rate of 36% for public health was again the lowest.

The over-all occupancy rate for all residencies was 84%, a gain of 2% over the previous year.

Residencies, by Type of Hospital Control

Table 8 reveals that 4,678 positions or approximately 15% of all positions are offered by the federal hospitals. Of the 124 federal hospitals offering residency positions, the Veterans Administration Hospitals offer 70%, or 3,263. These positions in Veterans Administration Hospitals were 75% filled on Sept. 1, 1958, and the figure of 2,453 represents 66% of the positions filled in all federal programs and 9% of the positions filled throughout the nation. Nonfederal governmental hospitals offered 11,289, or 35% of the positions while the nongovernmental, nonprofit hospitals offered the largest number of 15,518, or 49% of the positions. The 225 positions in proprietary hospitals represented less than 1% of the total.

The group of nonfederal governmental hospitals had the highest percentage of either of the four groups, 87%, filled on Sept. 1, 1958. Within this group, city hospitals were most successful with 92% occupancy. The nongovernmental nonprofit group of hospitals was next with 84% of the available positions filled, but within that group the church-related hospitals filled only 77% of available positions while the other nonprofit hospitals filled 86%. The group of federal hospitals showed 80% occupancy, with the air force showing the lowest rate of 66% and the navy showing the highest rate of 90%. The overall rate for the proprietary hospitals was lowest of the four groups, being 78%.

Residencies, by Hospital Bed Capacities

Table 9 indicates the number of residencies according to classification by bed capacity. The total number of positions available in all hospitals is 31,713; and of this number, 17,065, or 54%, are offered by the hospitals of over 500 bed capacity. This group of hospitals had filled 87% of its total appointments on Sept. 1, 1958. The highest occupancy rate was 88% for the hospitals of 50 to 99 bed capacity, while the lowest figure of 73% was in the hospitals of less than 50 bed capacity, of which there were 19 with approved programs. Of the 1,265 hospitals offering approved residency training programs, over three-fourths had more than 200 beds.

Residency Stipends

While the Directory of Approved Residencies has listed the beginning stipend for many years, no information has been available on the range of stipends offered in subsequent years of the programs. The supplemental questionnaire referred to earlier attempted to secure information on this subject. Hospitals were asked to list the average stipend which a resident would receive if he were to serve each year of the total period for which each program was approved. Data were secured on the average monthly stipends for 4,358 programs including those Veterans Administration Hospitals which reported but excluded the stipends for the other federal services.

When divided by IBM methods into programs differing by $50 increments, it was found that 78% of the programs paid between $150 and $350 per month. The actual figures and percentages were: $150-199, 813 programs, 19%; $200-249, 876 programs, 20%; $250-299, 977 programs, 22%; $300-349, 741 programs, 17%.

Maintenance

Data were analyzable from 4,336 programs indicating whether full, partial, or no maintenance was provided in addition to the stipend. Of this total, 2,437 programs or 56% provided full maintenance; 1,090, or 25%, provided partial maintenance; and 809, or 19%, provided no maintenance. Those programs indicating special provisions for married residents were catalogued as providing partial maintenance. It is felt these figures are sufficiently significant to warrant inclusion in future Directories with the initials FM and PM along with the stipends as is now done for the internship listings.

Additional Benefits

The supplementary questionnaire asked hospitals to indicate if Blue Cross or some other form of hospitalization was provided to the residents in addition to the residents' stipend. Of the total of 5,409 programs reported, 2,713 indicated that some form of hospitalization was provided. This is 50% of all the programs offered. The hospitals were also asked whether liability (malpractice) insurance was provided the residents in addition to the residents' stipend, and 1,981 programs, or 37%, replied affirmatively. Many hospitals replied that they carried liability insurance for the hospital, but these replies were not considered in the 37% reported here.

Residency Program Structure

An attempt was made in the supplementary questionnaire to determine the number of programs offering fewer residency positions each successive year in pyramidal fashion, offering reappointments to all residents for each year of the total program in vertical fashion, or following some other scheme. Of the 4,495 programs reporting, the great majority of 3,582, or 80%, indicated their organization was vertical. 560, or 12%, indicated the program structure was pyramidal, and 353, or 8%, indicated some other structure was in effect.

Table 10.—*Foreign Medical Graduates Reported as Residents, by Specialty, 1958-1959*

Allergy	5

Pulmonary Disease (including 71 in Tb)	113
Urology	127
Hospital Administration	3
Research (Unspecified)	8
Unknown (No field given)	175
Total	6,042

Further analysis of the two programs offering the largest number of appointments, general surgery and internal medicine, revealed that for the 567 surgical programs reported, 64% were vertical, 22% pyramidal, and 13% other. For the 511 internal medicine programs reported, 70% were vertical, 21% pyramidal, and 9% other.

Graduate Trainees Other than Residents

Because the term "fellowship" has come to be interchangeable with the term "residency" in some situations, and therefore leads to confusion, the term has been dropped both from the "Essentials of Approved Residencies" and from the Directory. The supplementary questionnaire attempted to identify the number of fellowship appointments to physicians serving in some other capacity in the hospital than in an approved residency training program. An additional question on "traineeships" was also included to further widen the scope of the inquiry.

While there was difficulty on the part of some hospitals in replying to this question, there were analyzable replies from 5,251 programs reporting residents and additional fellows or trainees. Those hospitals with fellowship and traineeship appointments were almost exclusively affiliated with medical schools. For this group of hospitals reporting on 5,251 residency training programs, there were 15,145 residency positions and 2,410 other types of graduate training appointments. There were 1,672 fellowships and 738 traineeships reported for physicians whose appointments were for other purposes than participation in residency training programs.

Some institutions make fellowship appointments to physicians for the primary purpose of enabling them to receive residency training in approved programs. The Council regards all such positions as residency positions, for purposes of classification. but there is no accompanying intent to change the Council's relationship to programs identified by the sponsoring institution under the term "fellowship".

Since an unknown number of physicians may be pursuing forms of specialty training other than residencies which are fully creditable by the American specialty boards towards certification, questionnaires in future years will attempt more accurately to determine the total of such trainees serving in those hospitals having approved residency training programs. The replies on the stipends for fellowships and traineeships were not analyzable, and no report can therefore be made.

Foreign Medical Graduates

Previous reference has been made to the generous cooperation of the Institute of International Education in providing the Council with data on foreign physicians serving in approved graduate training programs in the United States. During the year 1958-1959, 6,042 foreign graduate physicians served in approved residency training programs. This figure, added to the figure of 2,315 reported in the intern section, means that 8,357 foreign physicians served internships and residencies in the United States in 1958-1959. This figure is a correction of the figures reported in the publication "Open Doors, 1959" of the Institute of International Education where there were an additional 35 positions reported erroneously.

For the academic year 1957-1958, 38% of the foreign medical graduates were in their first year of American graduate training. For the year 1958-

1959, 3,040 foreign graduates (36%) were in their first year of American training. This would appear to indicate that approximately 725 of the foreign medical graduates secured residency appointments in their first year of American training.

Table 10 indicates the distribution of foreign graduates reported to the Institute of International Education who were appointed as residents in hospitals with programs approved by the Council. It will be noted that the specialty designations do not agree in all particulars with those used by the Council, and in some instances must include research assignments in special fields of medicine and even in dentistry and hospital administration.

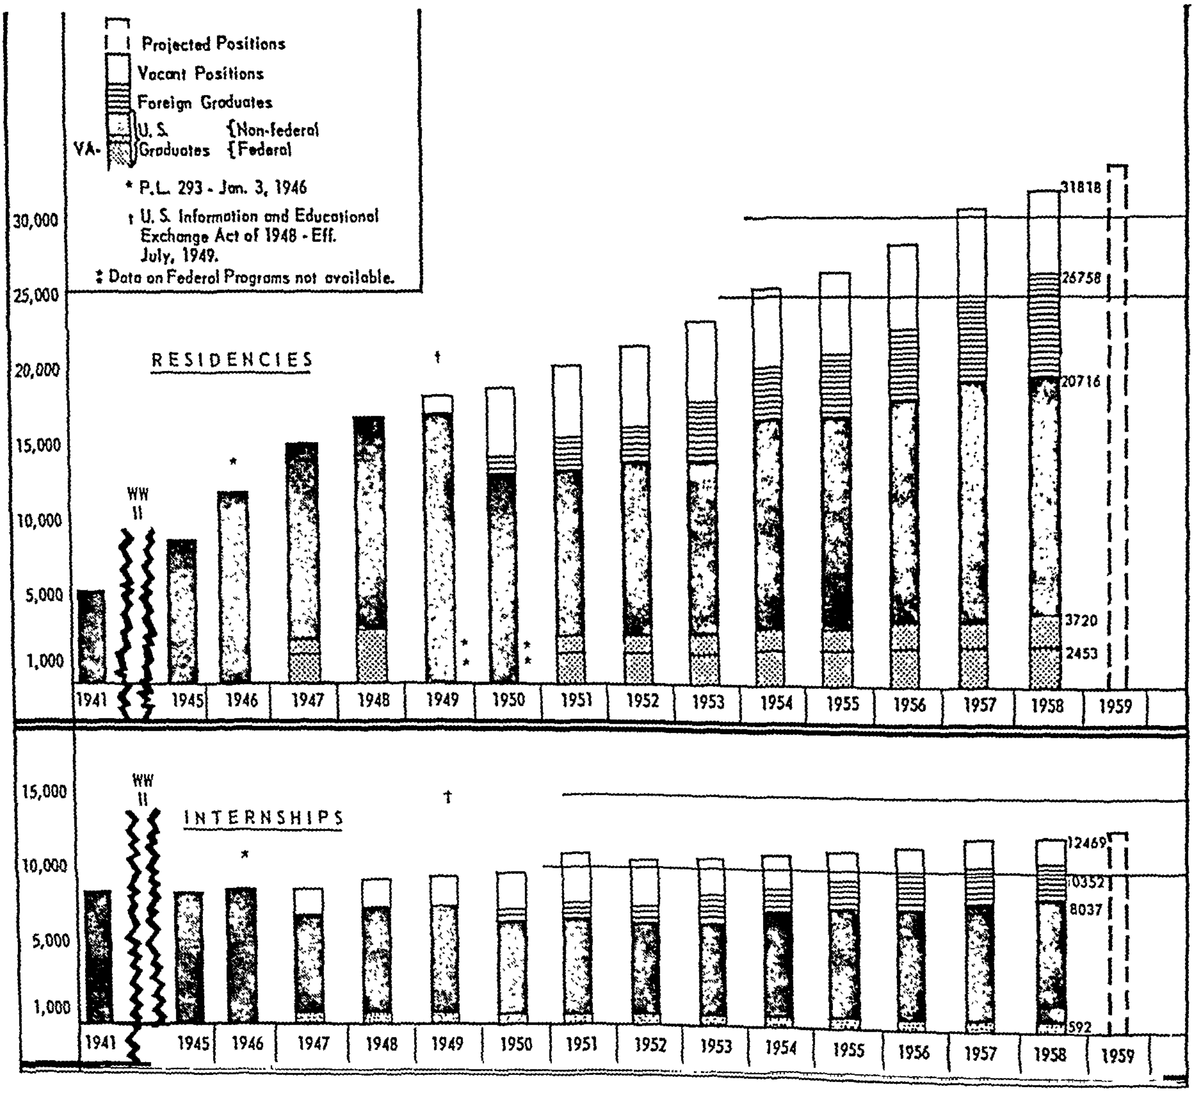

Fig. 2.—Status of Internship and Residency Programs in the United States.

The report for 1960 will indicate those foreign medical graduates appointed for the year 1959-1960 who secured certification by the Educational Council for Foreign Medical Graduates, and will also distinguish between those serving primarily as residents and those serving primarily in research or teaching positions.

Status of Internship and Residency Programs Since World War II

Figure 2 is a composite showing the expansion in graduate training programs which occurred after World War II, and includes not only the proportion of these programs supported by the federal government but also the positions filled by foreign medical graduates.

While the increase in available internships from 1941 to 1958 has been approximately 50%, the increase in residencies from 1941 to 1958 is approximately 500%. Prior to World War II, there were more approved internship appointments available than there were residency appointments. In 1941 there were 8,182 internships, and 5,256 residencies. In the immediate postwar years, even though the federal services inaugurated graduate training programs in 1946, available residency positions had increased over threefold to 17,293 in 1948 with all positions filled. This marked expansion was occasioned by the desire of young physicians discharged from military service to secure specialty training to a degree wholly at variance with the pre-World War II pattern. In 1948, although approximately 3,000 positions were available in federal hospitals, there were still approximately 14,000 positions in nonfederal hospitals in contrast to the 5,256 residencies in 1941, and 8,930 in 1945.

In 1948, a significant step was taken by Congress in passing the United States Information and Educational Exchange Act of 1948, effective in July of 1949. This action facilitated the securing of visas for educational purposes by foreign students, and the chart reveals that the participation of foreign medical graduates in American internship and residency programs first became significant in 1950. For the years 1950 through 1953, the number of approved residencies increased each year, but the number of American graduates securing residency appointments remained almost static. These were the years when the effects of the Korean war were being felt most strongly by training programs, and accordingly there was an increasing demand for foreign graduates to fill the vacancies existing.

Since 1954, there has been a slight increase in the number of American graduates filling internship positions and a more marked increase in those filling residencies. While the number of foreign medical graduates continues to increase each year, the increased total positions offered maintains the proportion of unfilled internships at approximately 2,000 and of unfilled residencies at approximately 5,000.

Figure 2 indicates that the passage of Public Law 293 on January 3, 1946 enabled the Veterans Administration to inaugurate internship and residency training programs. The uniformed federal services also inaugurated such programs in that year. For the past twelve years, therefore, the size of the programs supported by the federal services has remained relatively constant in the face of the slow increase in internships and the continued increase in residencies. While the uniformed services place emphasis on their internship programs, the participation of the Veterans Administration in the conduct of internship programs is almost non-existent. On the other hand, over the years, approximately 70% of the federally supported residency positions are in Veterans Administration Hospitals. Figure 2 makes it clear that the entry of the federal government into the support of internship and residency programs in 1946 was only part of a more general movement on the part of hospitals throughout the United States. It is furthermore clear that once the federally supported programs had attained a fixed level, they varied little from year to year, while approved programs and available positions in nonfederal hospitals have progressively increased at a modest rate for internships but at a startling rate for residencies.

The announcement by the Department of State on April 24, 1959 of the five year limit on the stay of foreign medical graduates serving internships and residencies in this country will undoubtedly reduce the number of foreign graduates attempting to remain in the United States longer than necessary for the purposes of the Exchange-Visitor program authorized by the United States Information and Educational Exchange Act of 1948. There are instances in which foreign medical graduates have served continuously in this country in graduate training programs for as long as ten years. This action of the State Department is in support of the intentions of the Congress of the United States that the exchange-visitor should return to his homeland to foster abroad a better understanding of our way of life.

Résumé

The 33rd annual report contains statistical data bearing on past performance and future trends of approved graduate training programs in the United States, its territories and possessions; it includes the performance data for existing programs for the year 1958-1959 and also the Directory of Approved Internships and Residencies with positions offered for July 1, 1960; and it contains the latest performance figures and requirements for certification of the American specialty boards. This report will be of use to all recent American medical graduates, many foreign medical graduates, and all other personnel concerned with the administration and planning of graduate medical programs.

The number of approved internships, 12,469, increased by only approximately 1% over the preceding year. The number of approved residencies, 31,818, increased by only 4% over the previous year. The occupancy rate for internships remained at 83%, the same figure as for the three previous years. The occupancy rate for residencies as of September 1, 1958 was 84%, an increase of 2% over last year's figure.

At the present time, the number of hospitals and other institutions offering graduate training stands at 1,435. The Directory of Approved Internships and Residencies contained in this annual report indicates that 137 (10%) hospitals offered intern training only, 576 (40%) offered resident training only, and 722 (50%) were approved for both intern and resident training.

APPROVED INTERNSHIPS

Council on Medical Education and Hospitals of the American Medical Association
535 North Dearborn Street, Chicago 10

Revised to September 1, 1959

HOSPITALS, 859 INTERNSHIPS, 12,887

The following general hospitals, investigated and approved by the Council on Medical Education and Hospitals, are considered in position to furnish acceptable intern training in accordance with standards adopted by the American Medical Association. Three types of internships are approved by the Council—rotating, mixed, and straight:

1. A rotating internship is defined as one that provides supervised experience in internal medicine, surgery, pediatrics, obstetrics, and their related subspecialties, together with experience in laboratory and radiologic diagnosis.
2. A mixed internship is defined as one that provides supervised experience in two or more, but not in all, of the clinical divisions named.
3. A straight internship is defined as one that provides supervised experience in a single department, although it may include limited opportunity for work in a related subspecialty. Straight internships are now approved in internal medicine, surgery, pediatrics, pathology, and obstetrics-gynecology.

Hospitals approved for internships that are used by medical schools for undergraduate clinical clerkships on inpatient services have been identified in the following lists by the symbols X and x. Hospitals have been identified with symbol X when a medical school has indicated that the hospital is a major unit in the school's teaching program. Hospitals have been identified with the symbol x when a medical school has indicated that the hospital is used to a limited extent in the school's teaching program. Certain internships in hospitals designated as teaching hospitals may not provide for assignments to teaching services. Other internships may provide for only a portion of the internship period being spent on teaching services. Prospective interns desiring specific information concerning internship assignments to teaching services in a hospital are advised to communicate with the dean of the medical school with which the hospital is affiliated. Medical school affiliations are indicated by footnotes 10 to 92 placed immediately after the symbol X or x. The list of medical schools appears on page 699. The plus (+) sign indicates additional approval for residencies in specialties, as shown in the Council's list of Approved Residencies. The beginning stipends for Federal hospitals have not been listed; they are established in accordance with government pay tables. When applying for internships in Air Force, Army, Navy, or Public Health Service hospitals, applications should be directed to the medical departments of the Air Force, Army, Navy, or the United States Public Health Service and not to the individual hospitals. Although applications are made to the service rather than to individual hospitals, all of the services ask students to list three hospitals in order of preference. Every possible effort is made to place successful candidates in accordance with their desires. Because of the needs of the service it should be understood that students may, in some instances, be assigned to other hospitals than those for which they have indicated preference.

Hospitals listed below (pages 675 to 698) make first year internship appointments through the National Intern Matching Program, Inc. The number and type of internships as listed represent appointments for the intern year 1960-1961.

Hospitals designated with an asterisk (*) in this listing do not participate in the National Intern Matching Program, sponsored by the American Medical Association, the American Hospital Association, the Association of American Medical Colleges, and other cooperating organizations. Abbreviations and other references will be found on pages 699 through 701.

HOSPITALS APPROVED FOR JUNIOR ROTATING INTERNSHIPS IN THE DOMINION OF CANADA

The following list of hospitals that conform to the standards of The Canadian Medical Association is published for the information of graduates interested in an internship appointment in a Canadian hospital. Hospitals that are approved as conforming to the standards of The Canadian Medical Association may be considered as offering internships equivalent in educational value to those in hospitals approved for intern training by the Council.

This list, revised to July 1, 1959, was furnished by The Canadian Medical Association.

ABBREVIATIONS AND NOTES

1. Appointments available to women applicants
2. Appointments restricted to women applicants
3. Appointments available to graduates of foreign medical schools. Details regarding requirements for appointment can be secured from the hospitals concerned.
4. Dental internships available
5. Available to citizens of the United States only

+ The plus sign indicates additional approval for residencies in specialties, as shown in the Council's list of Approved Residencies.

CyCo	City and County
Corp	Corporation unrestricted as to profit
Dist	Hospital District
NPCorp	Nonprofit corporation
Part	Partnership
Req	Required
FM	Full maintenance
PM	Partial maintenance

Medical School Affiliations

Footnotes 10 to 92 refer to medical schools affiliated with hospitals for undergraduate clinical clerkships.

Hospitals have been identified with symbol **X** when a medical school has indicated that the hospital is a major unit in the school's teaching program. Hospitals have been identified with symbol **x** when a medical school has indicated that the hospital is used to a limited extent in the school's teaching program.

APPROVED RESIDENCIES

Council on Medical Education and Hospitals of the American Medical Association
535 North Dearborn Street, Chicago 10

Revised to September 1, 1959

Hospitals, 1,298; Residencies, 31,818

The following services are approved by the Council on Medical Education and Hospitals as meeting the requirements of the Essentials of Approved Residencies. In those specialties in which certifying boards have been established approval is extended in concurrence with the Board concerned as indicated. The number of years of training for which approval has been granted is indicated in the column, "Length of Approved Program (years)." Residencies in which this designation does not appear have been approved without specifying the number of years for which they are accredited. The beginning stipends for Federal hospitals have not been listed; they are established in accordance with government pay tables.
